
Data Mining in a complex world

Hugues Bersini
IRIDIA/CODE

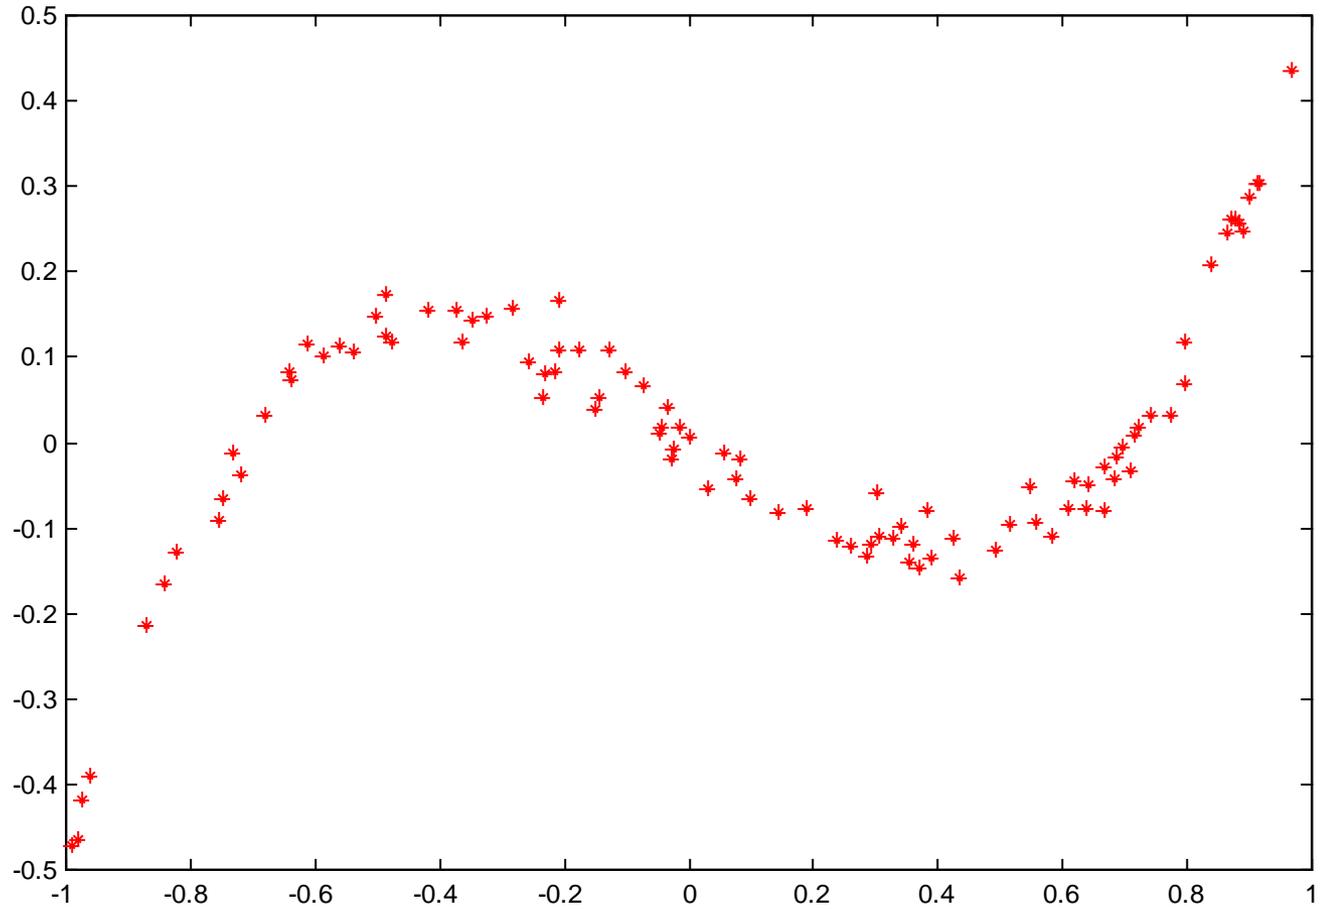

Modelling the data: WHY ??

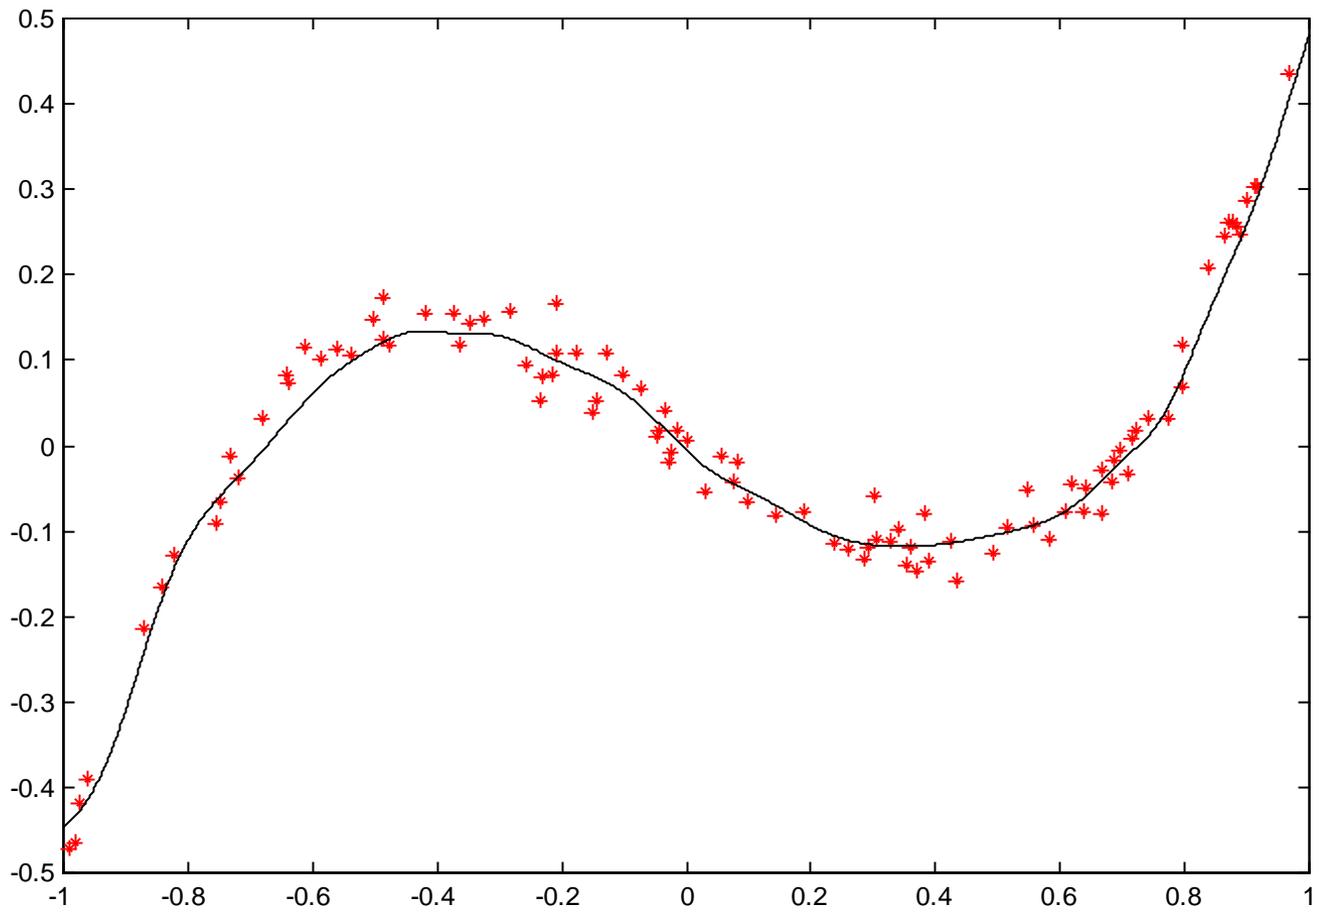

only if structure and regularities in the data
data contains the needed information in a hidden form !!

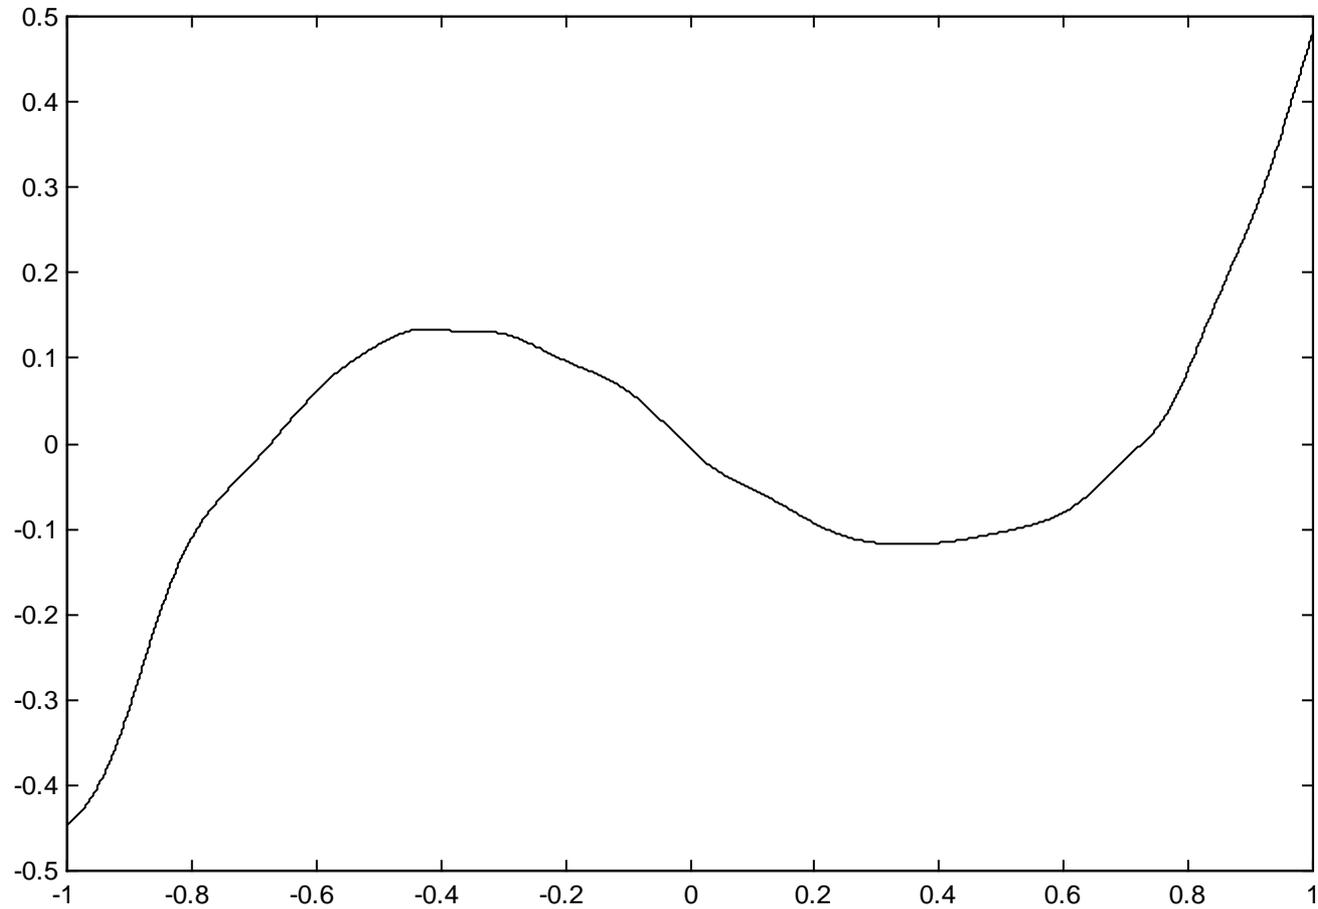

They might be antagonistic objectives

Training set

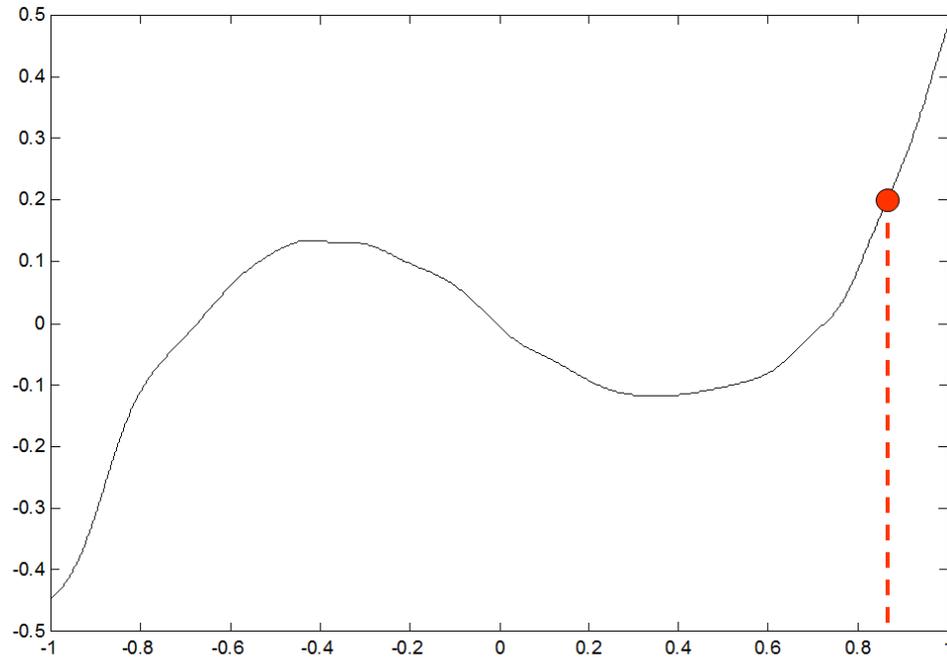

A compressed model with predictive power

Prediction with global models

The main techniques of data-mining

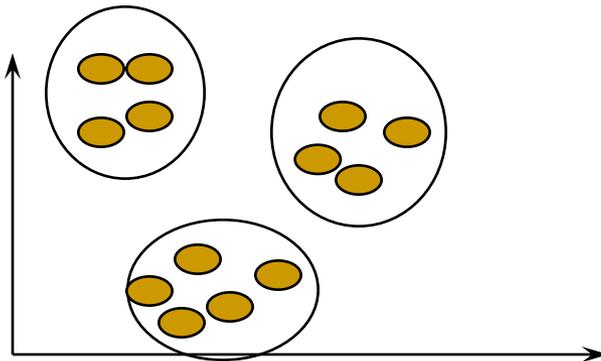

- Clustering
 - Classification
 - Outlier detection
 - Association analysis
 - Regression
 - Forecasting
 - Why in business: personalized business, improved prediction, targeted marketing
-

Data Classification: to understand and/or to predict

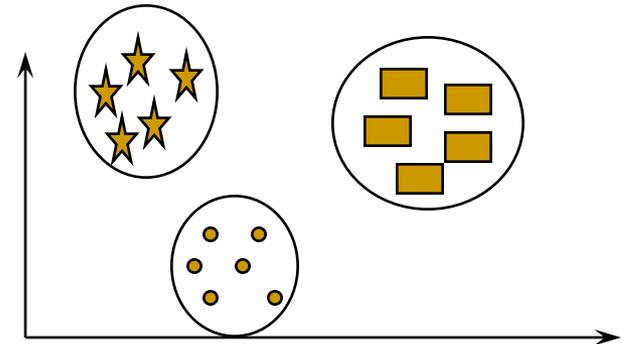

Clustering

Classification

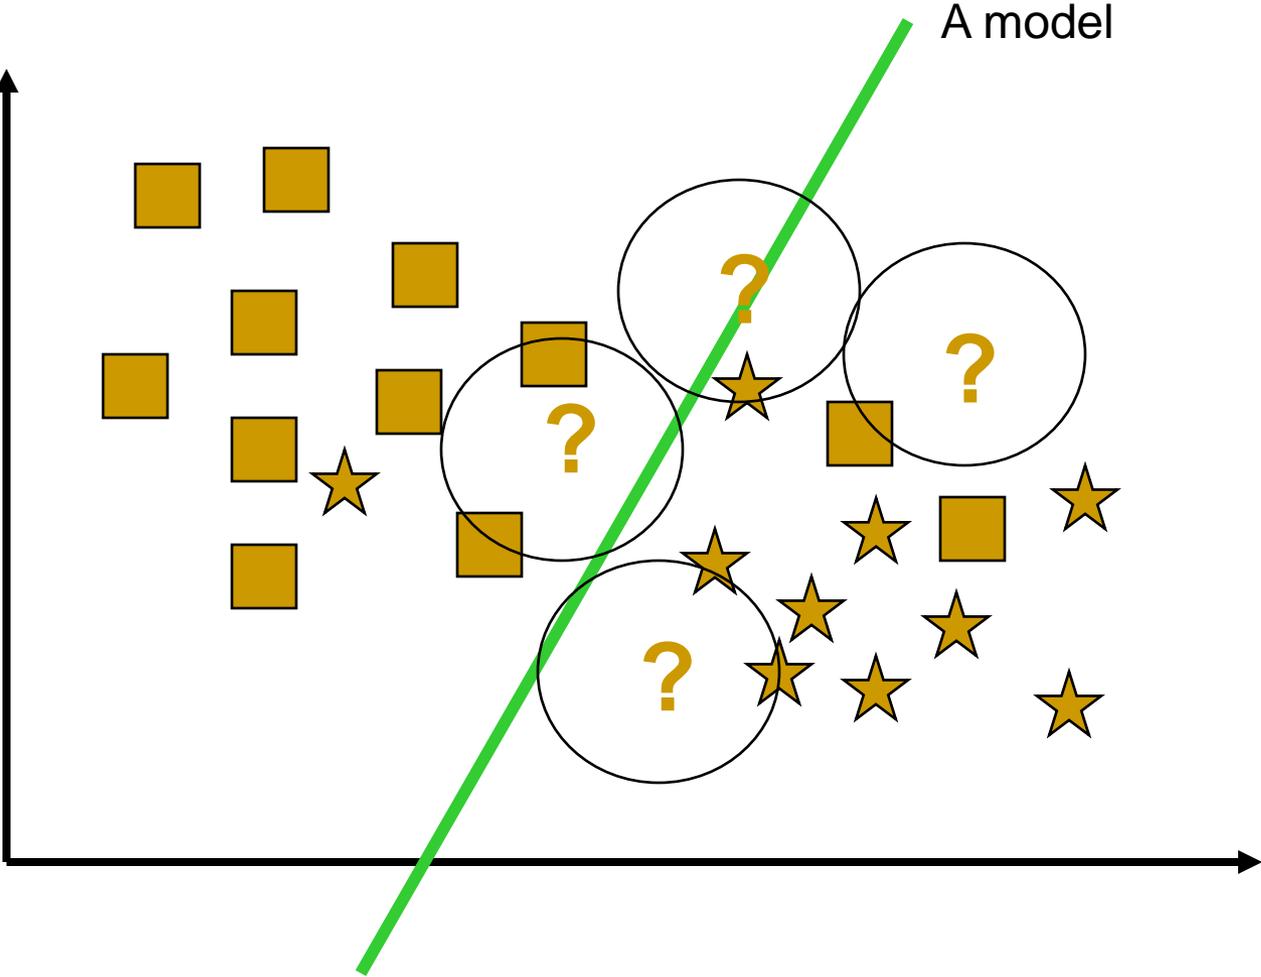

discovering structure in data

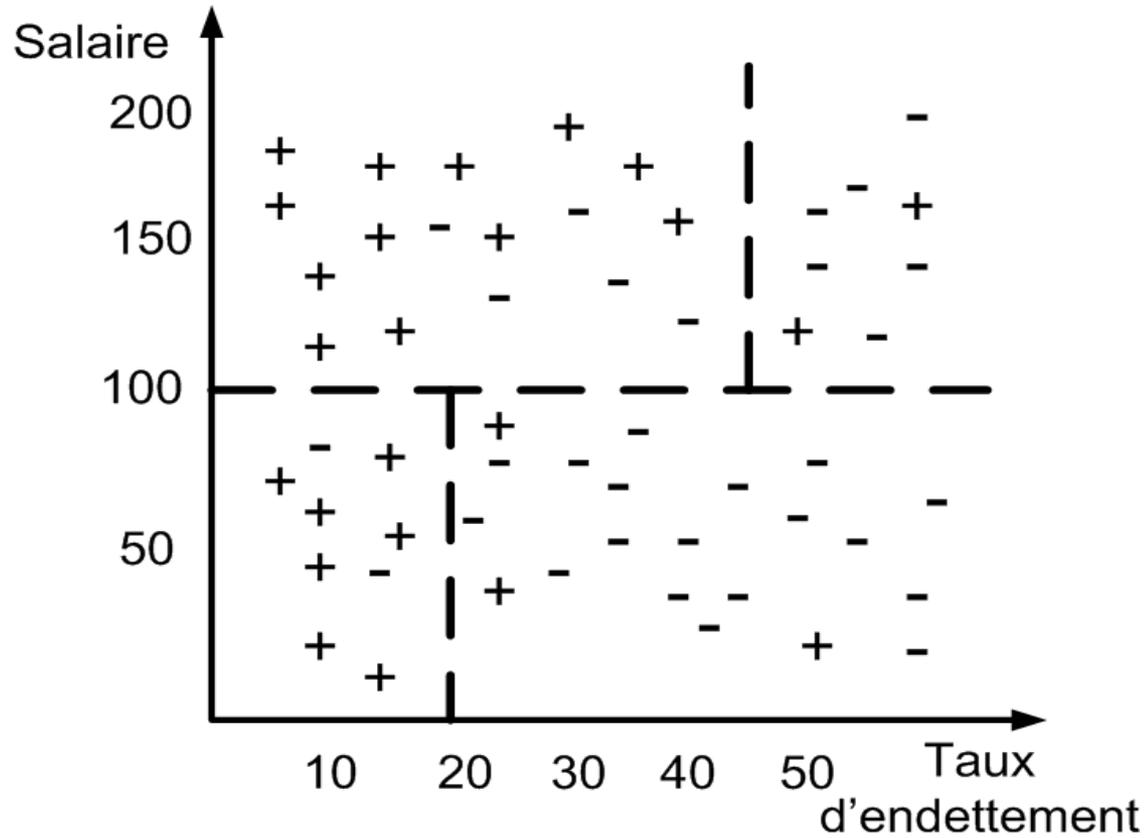

discovering I/O relationship in data

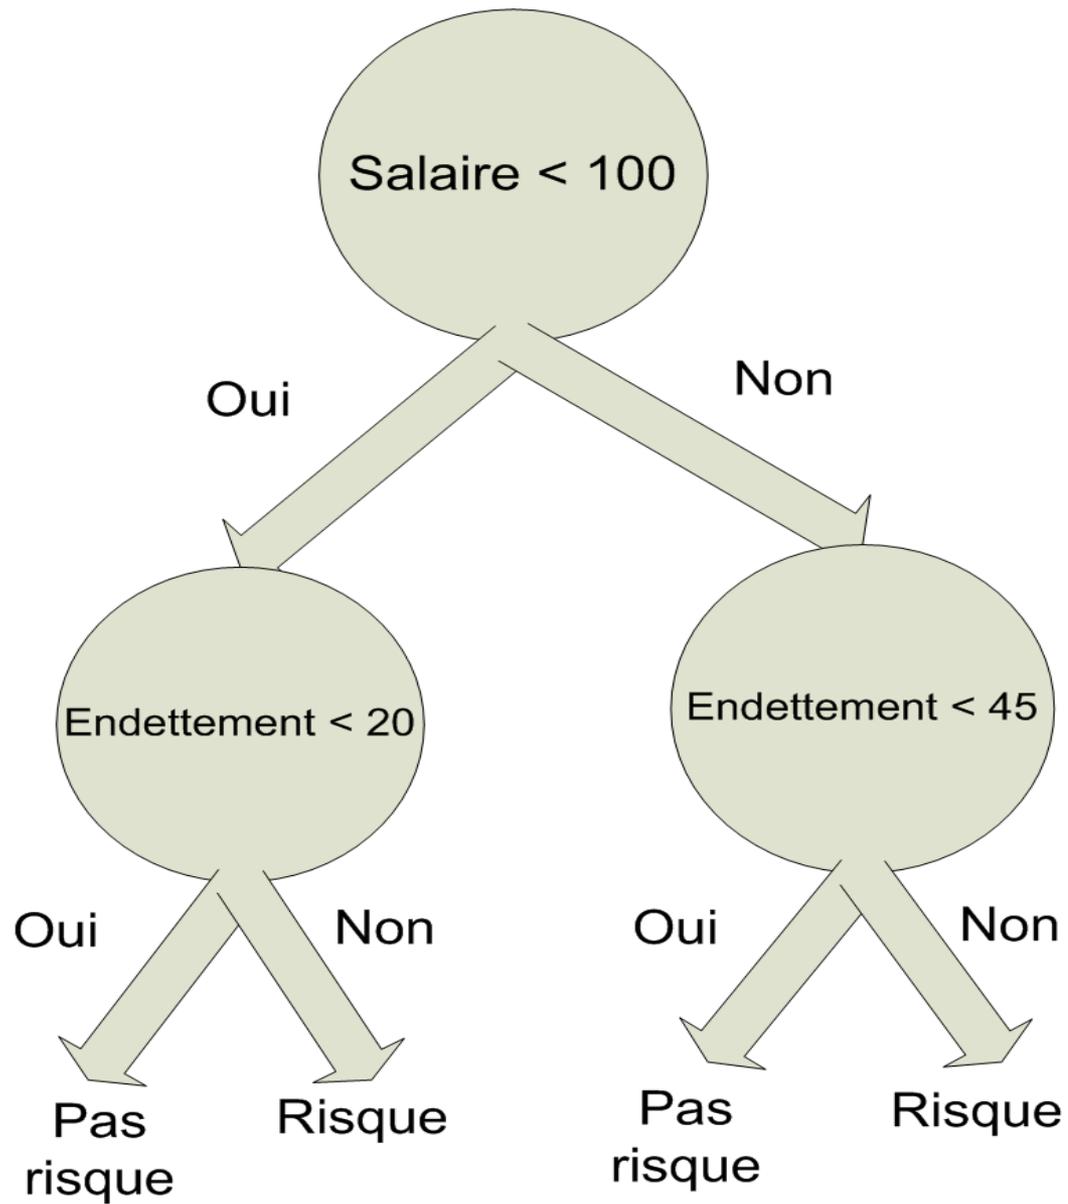

CLASSIFICATION

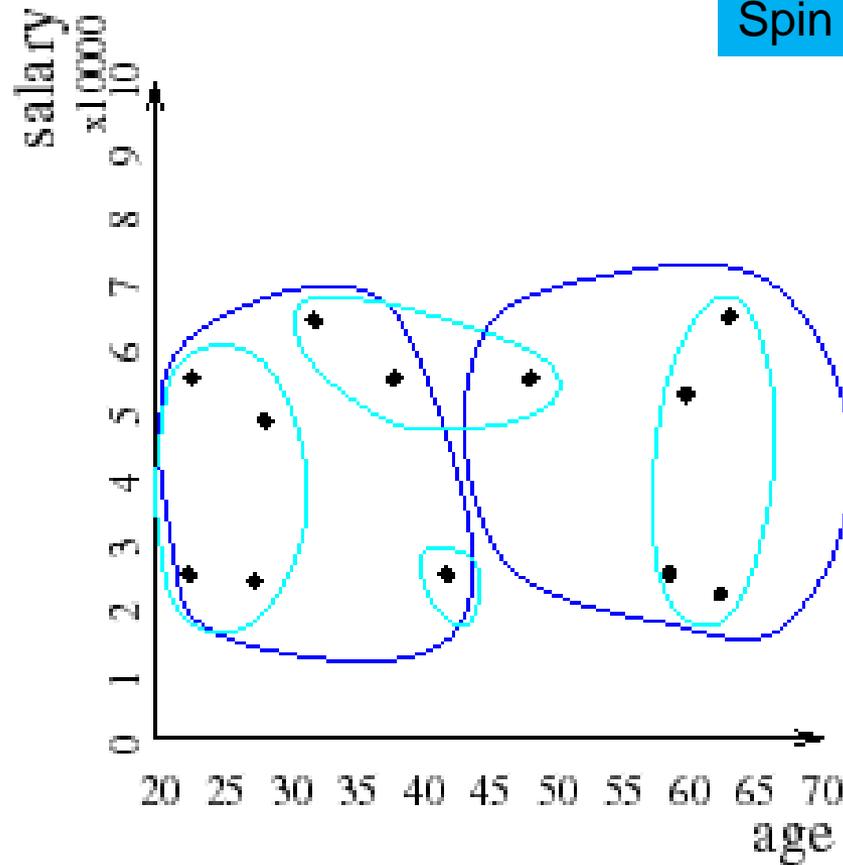

Exemple de classification: Decision tree

Clustering and outlier

Spin off : VADIS

Important emblematic achievements

1) A new engineering approach

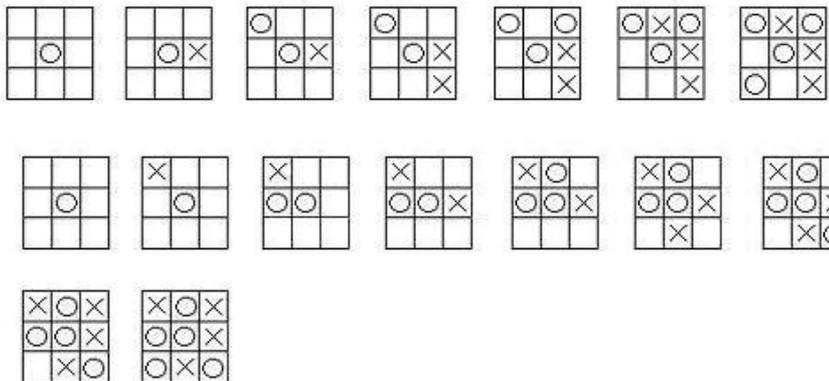

The Darpa Challenge

Games

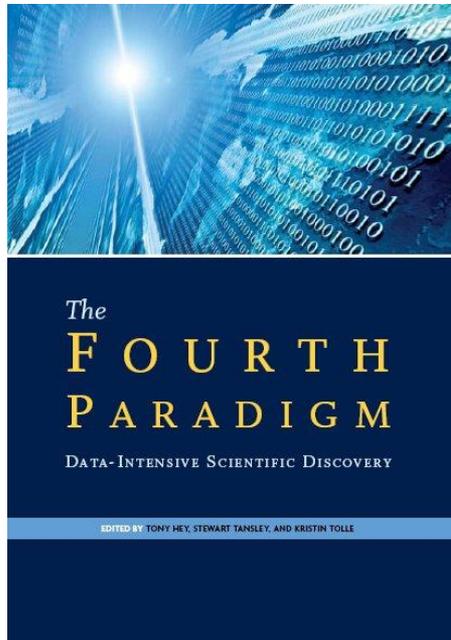

Min-max

Data mining

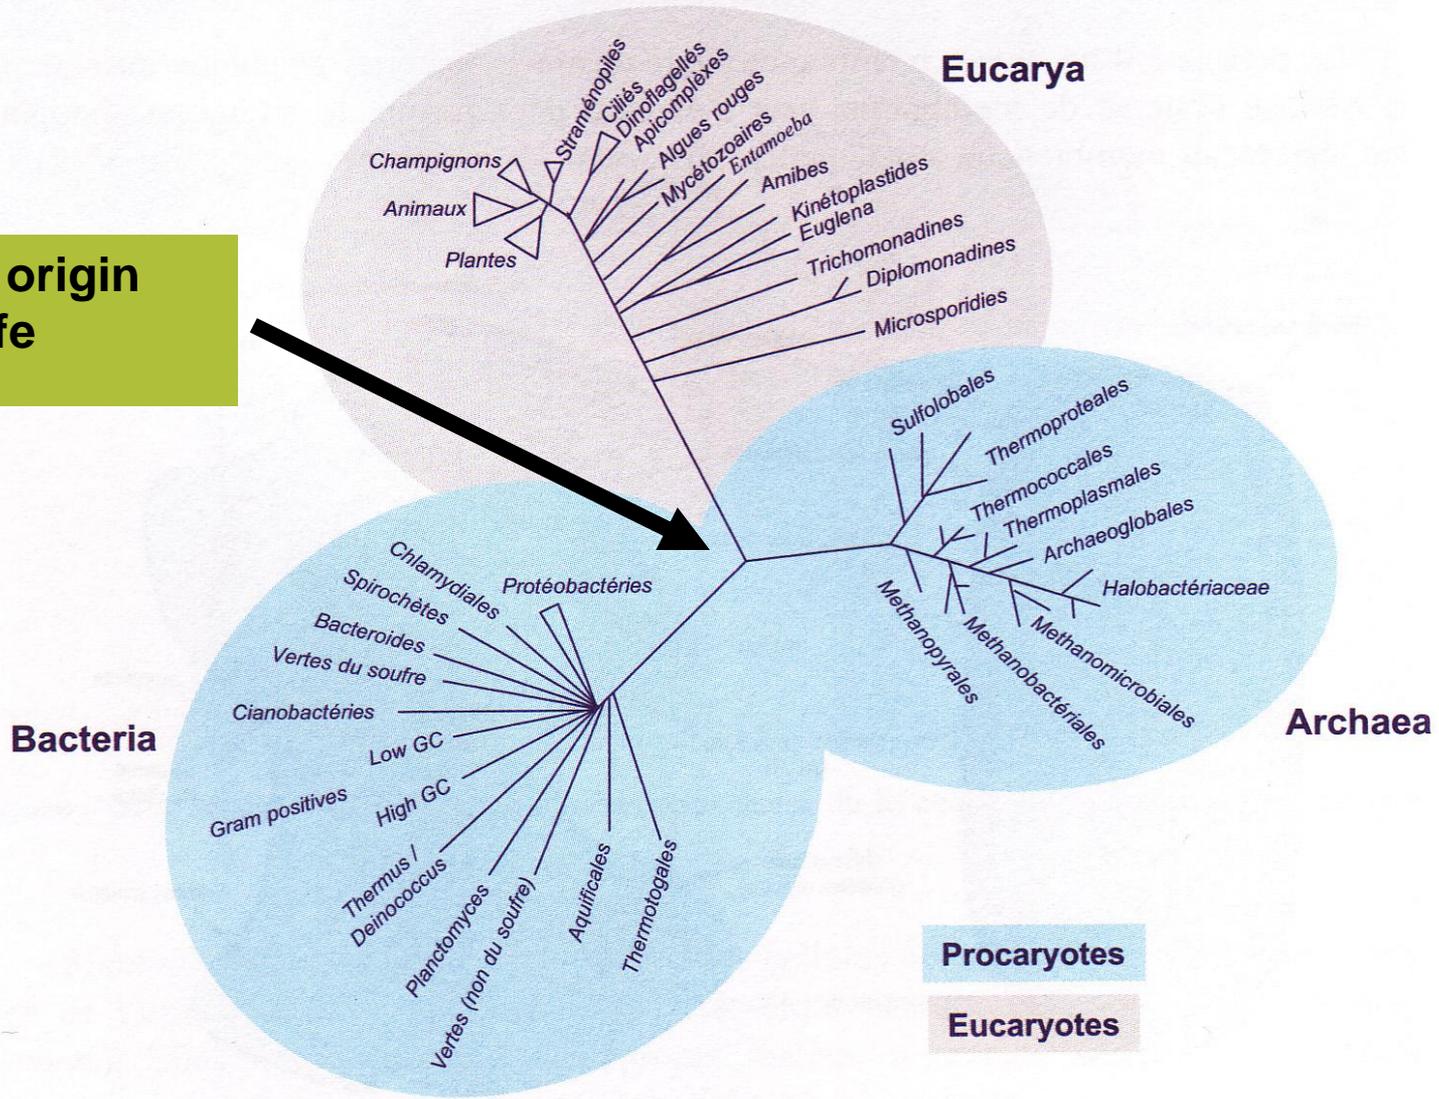

2) A new scientific Paradigm: The fourth : Microsoft

Increasingly, scientific breakthroughs will be powered by advanced computing capabilities that help researchers manipulate and explore massive datasets. The speed at which any given scientific discipline advances will depend on how well its researchers collaborate with one another, and with technologists, in areas of eScience such as databases, workflow management, visualization, and cloud computing technologies.

SMART : detection of outlier clinical site

- Real example
 - Known fraud in center 191
- SMART analysis
 - 191 is an outlier
- Other centers?
 - 141, 155, 165?
 - Most frauds are undetected by current methods

Summary through PCA of a SMART analysis

The future of it: More and more free documents with various contents and various own structuration

Art Mining:

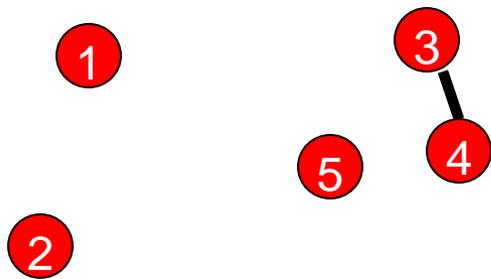

- images
- musics
- movies

Exemple of clustering: hierarchical clustering

Algorithm

- • *Join the two closest elements.*
- Update the distance matrix.

Closest : 3 et 4

| | 1 | 2 | 3 | 4 | 5 |
|---|---|----|----|----|----|
| 1 | 0 | 10 | 15 | 18 | 12 |
| 2 | | 0 | 23 | 22 | 13 |
| 3 | | | 0 | 4 | 6 |
| 4 | | | | 0 | 5 |

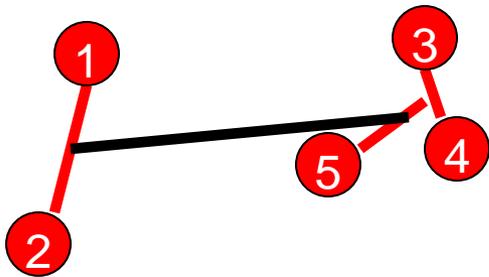

Distance matrix

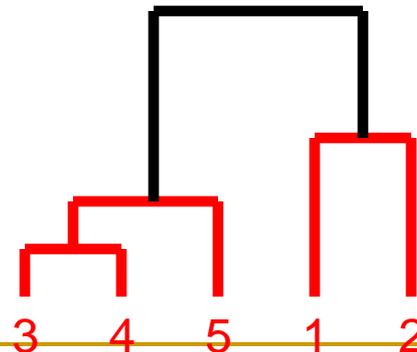

Hierarchical clustering

Algorithm

- • *Join the two closest elements.*
- Update the distance matrix.

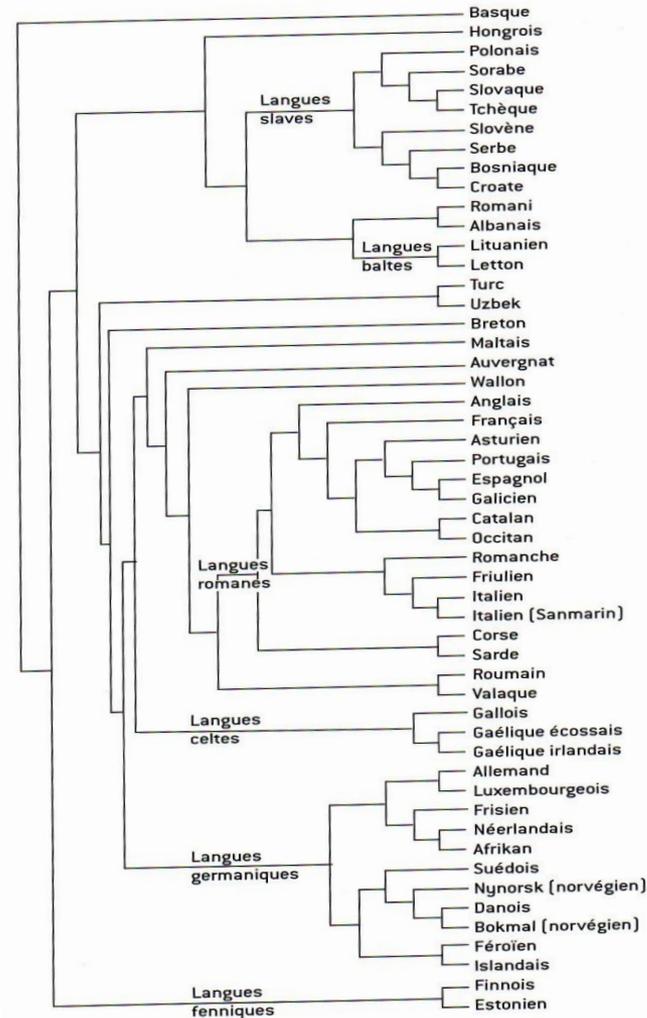

Closest : (1,2) et (3,4,5)

Similarity based on compression algorithm

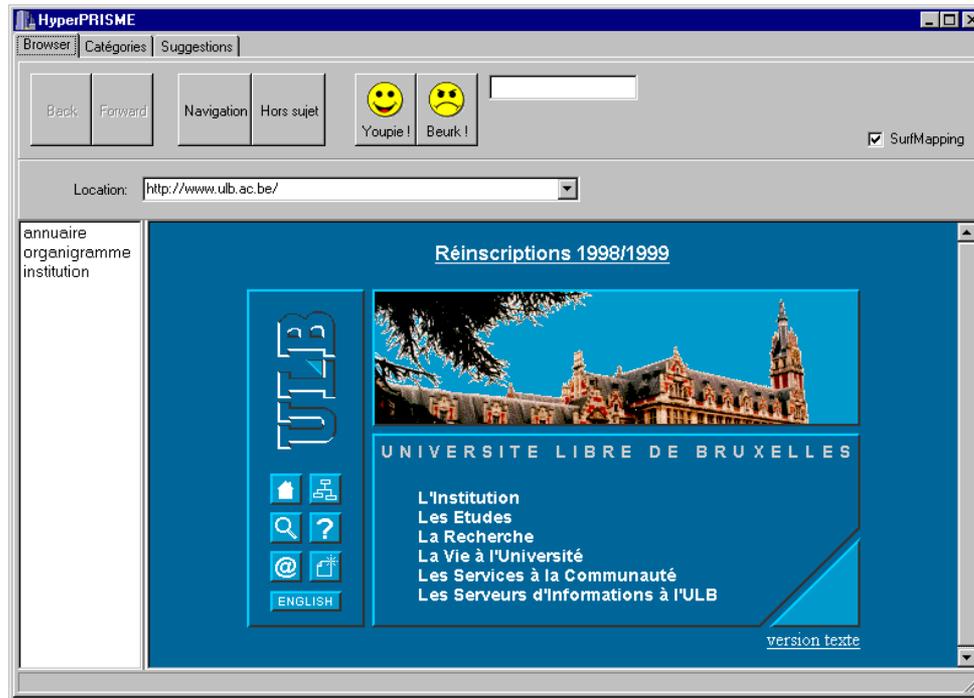

- Suppose two documents A and B
- Compute length of compressing A: $C(A)$
- Compute length of compressing B: $C(B)$
- Compute length of compressing AB: $C(AB)$
- Similarity $(A,B) = 1 - [C(A) + C(B) - C(AB)] / C(A)$
if $C(A) \geq C(B)$

Similarity between natural languages

Web Mining

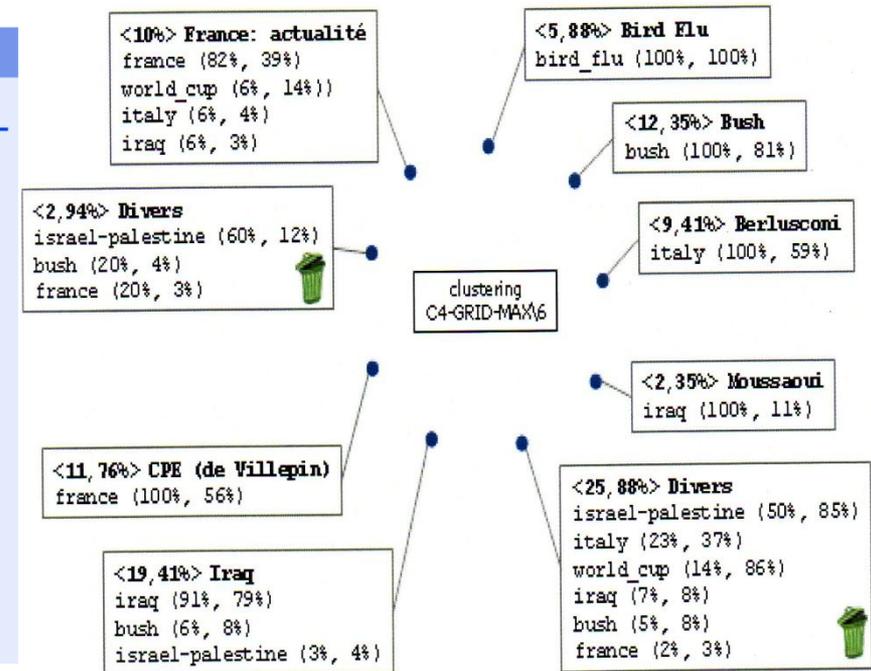

- The Hyperprisme project
- Spy the user and mine his clickstream
- Automatic profiling of users
 - Key words: positif, negatif,...
- Automatic grouping of users on the basis of their profiles

Text Mining: still a lot of possible improvements

Exploit the graph structure of XML + the content between the tags

We are working on Wikipedia

The Nature of Wikipedia

- Wikipedia is a combination of two interconnected graphs
 - A directed graph with the regular pages as nodes and the links between pages as edges
 - An acyclic directed graph with the category pages as nodes and their connections as edges
- The main regular page graph consists of ~ 3 650 000 nodes and the category graph of ~ 700 000 nodes (last count)

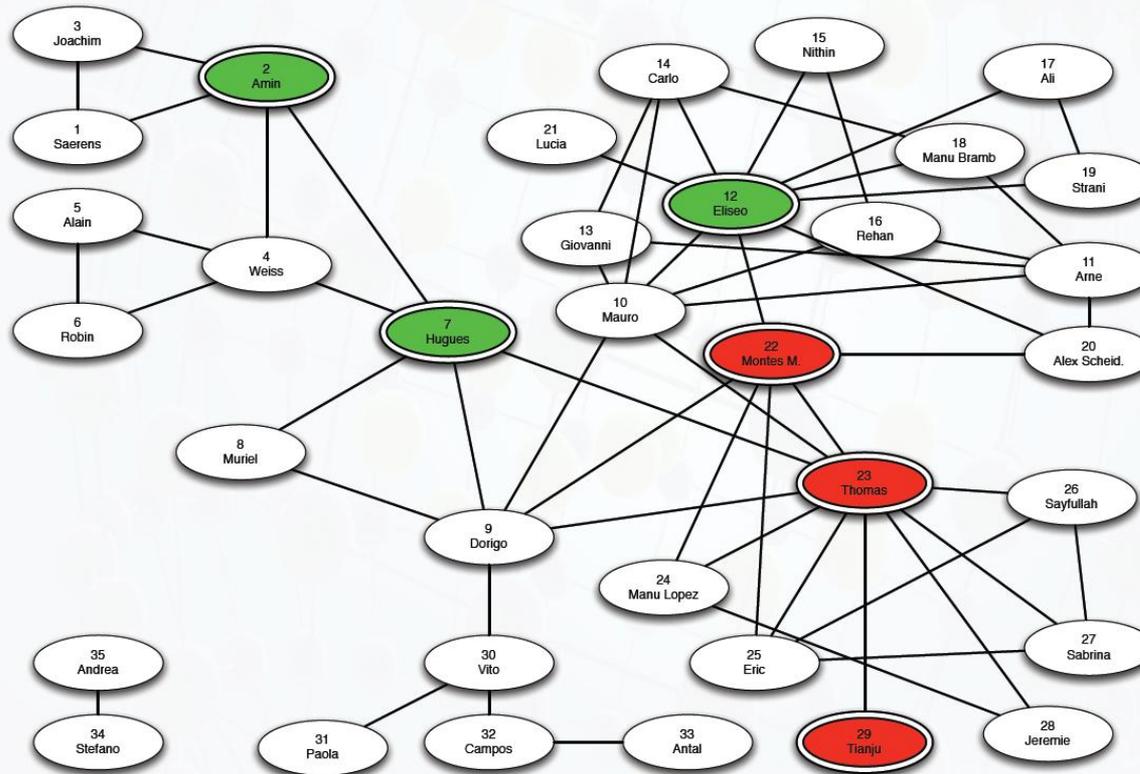

Graph Mining

Introduction and Context
Betweenness and Covariance
Classification of Nodes
Conclusion and Perspectives

Introduction
Algorithms
Experiments

Application to Classification

Let us classify all the nodes.

Combine different types of information: graph and text

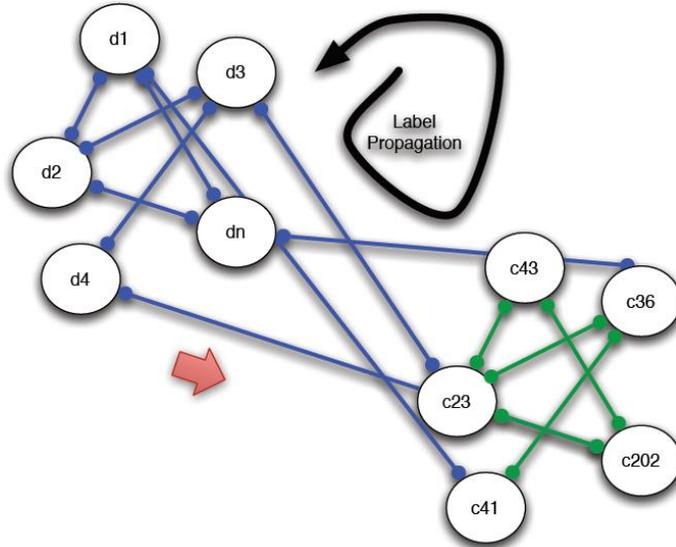

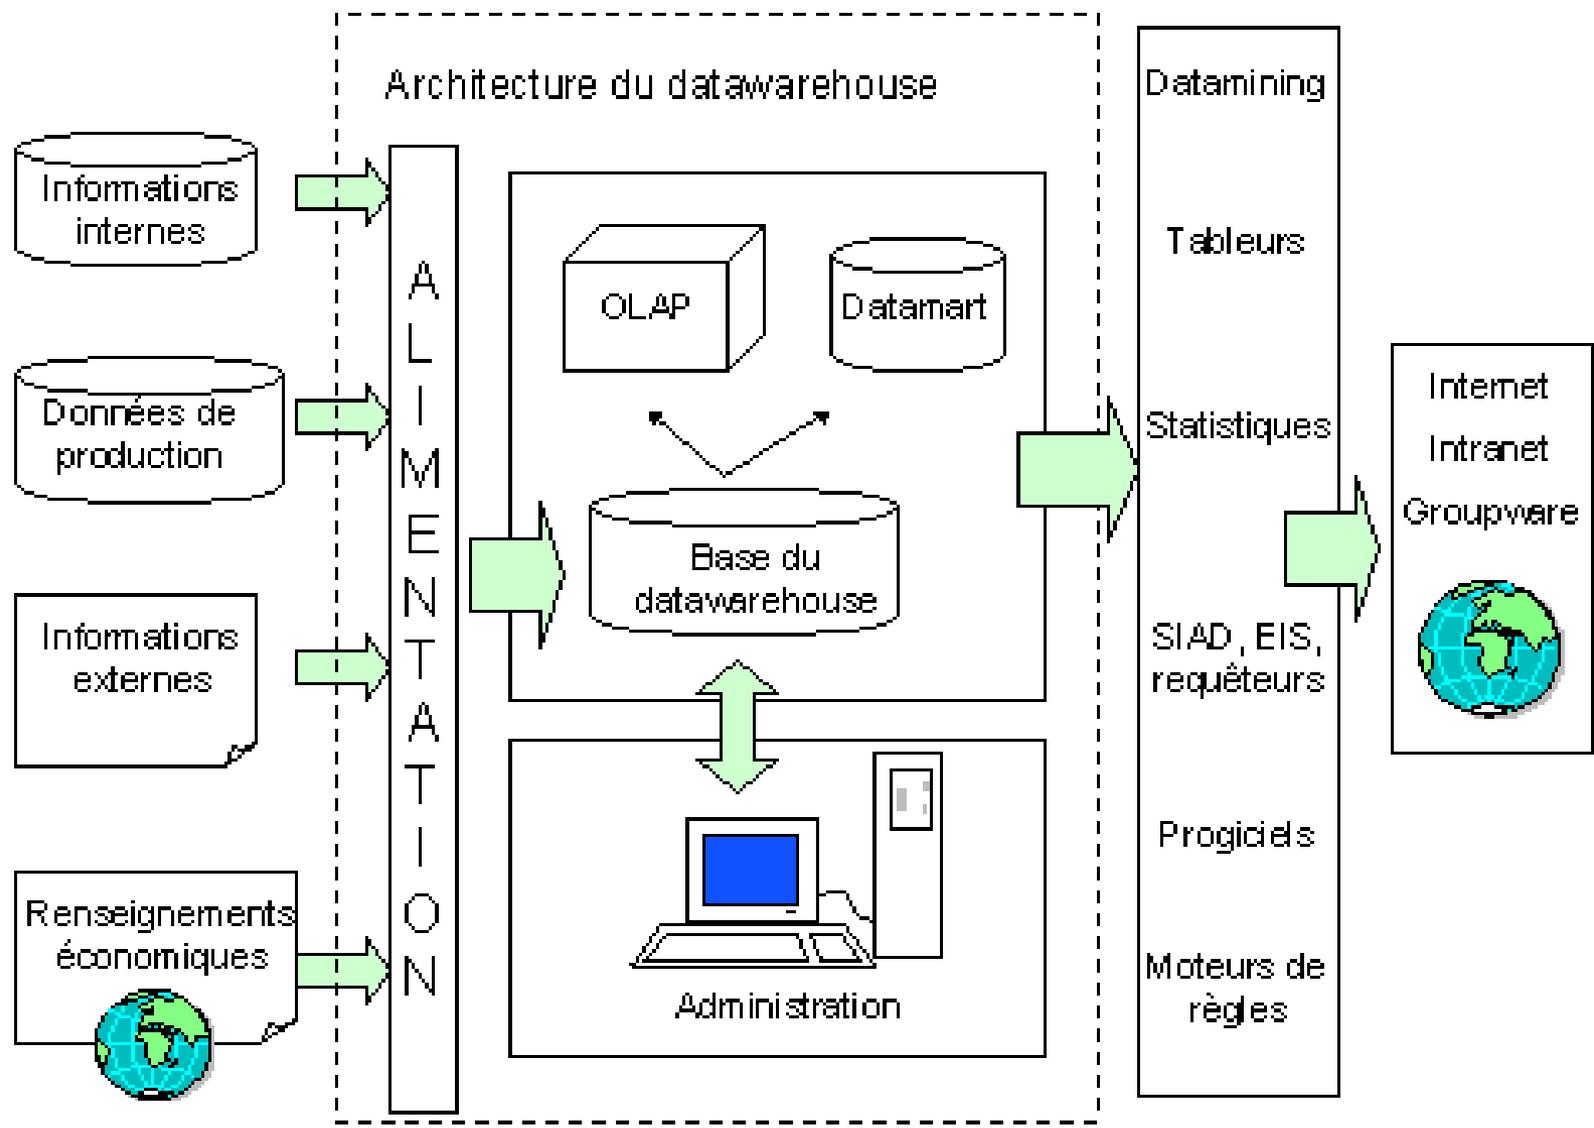

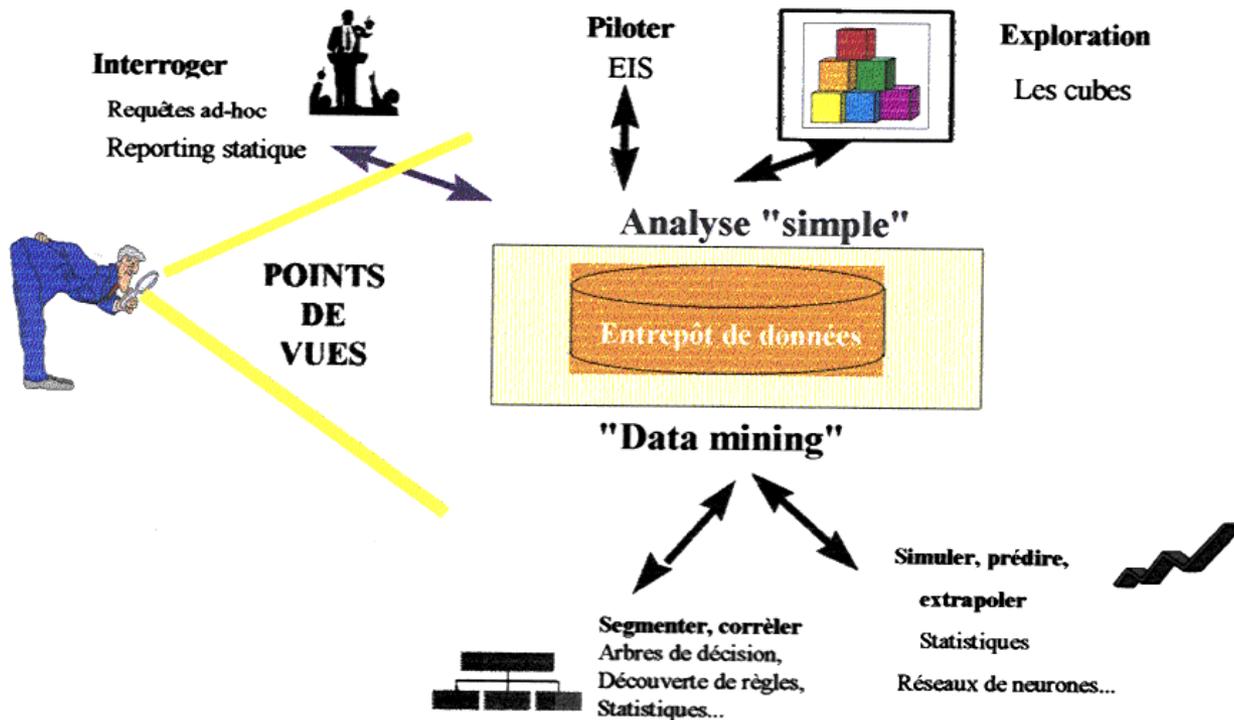

Figure 10: The document nodes has been connected to an external preexisting citation network through inferred k nearest neighbors links (i.e. in blue). The goal is to propagate labels from the citation graph to the just connected documents.

Data Warehousing

Source : *Le Data Warehouse –Le Data Mining*, Eyrolles, Paris, p. 40

Réorganisation des données

- Orientées sujet
 - intégrées
 - transversales
 - historisées
 - non volatiles
 - Des données productions ---> données décision
-

| | Environnement transactionnel | Data Warehouse |
|--|--|---|
| Type d'utilisateurs | Font tourner les roues de l'entreprise | Vérifient si les roues de l'entreprise tournent bien |
| Définition de système performant | Système performant = système rapide | Notion de performance est liée au degré de prévisibilité d'une requête |
| Volumes manipulés | Faible | Elevé |
| Type d'accès | Lecture/écriture : la donnée est modifiée en ligne | Chargement par batch, mises à jour interdites car les données sont des clichés issus des systèmes de production |
| Types de données stockées | Dynamiques : mises à jour fréquente | Statique, évolution par chargement |
| Gestion des redondances | Est évitée car elle pose des problèmes d'incohérence de données | Redondance peut être nécessaire pour optimiser les performances → pas de problème de cohérence car la donnée de base est déjà une copie |
| Domaine couvert | Modèle le plus souvent propre à une application | Rôle transversal dans l'entreprise et organisé par sujet |
| Mode d'accès et conséquence sur le modèle de données | Par l'intermédiaire d'application ; le modèle de données n'est visible que par l'utilisateur qui ne voit le système qu'à travers des applications qu'il utilise → le modèle de données peut être complexe | Directe ou légèrement masquée par un outil d'aide à la décision → le modèle doit être simple |
| Type de requête | Simple car prévisibles → le modèle de données est conçu pour éviter les requêtes trop complexes. La plupart des requêtes s'appuient sur un index, d'où des temps de réponses proportionnels au volume stocké. Les performances sont stables car toutes les requêtes sont prédéfinies | Complexe, surtout si l'utilisateur est autonome. Il est quasiment impossible de garantir que tous les accès passeront par les index : le temps de réponse peut dépendre du volume stocké et pas seulement du volume associé au résultat de la requête |
| Horizon temporel | Court | Long |
| Nombre et type d'accès | Réguliers et prévisibles | Très irréguliers et imprévisibles |
| Volume | Rarement supérieure à la dizaine de gigas | Supérieur car historisation |

Métriques

Model-based vs Data-based

Different approaches

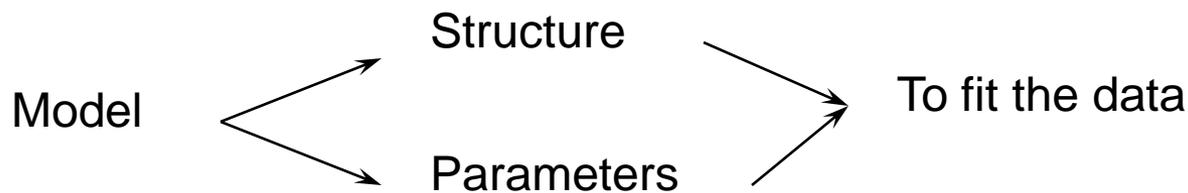

Understanding and Predicting

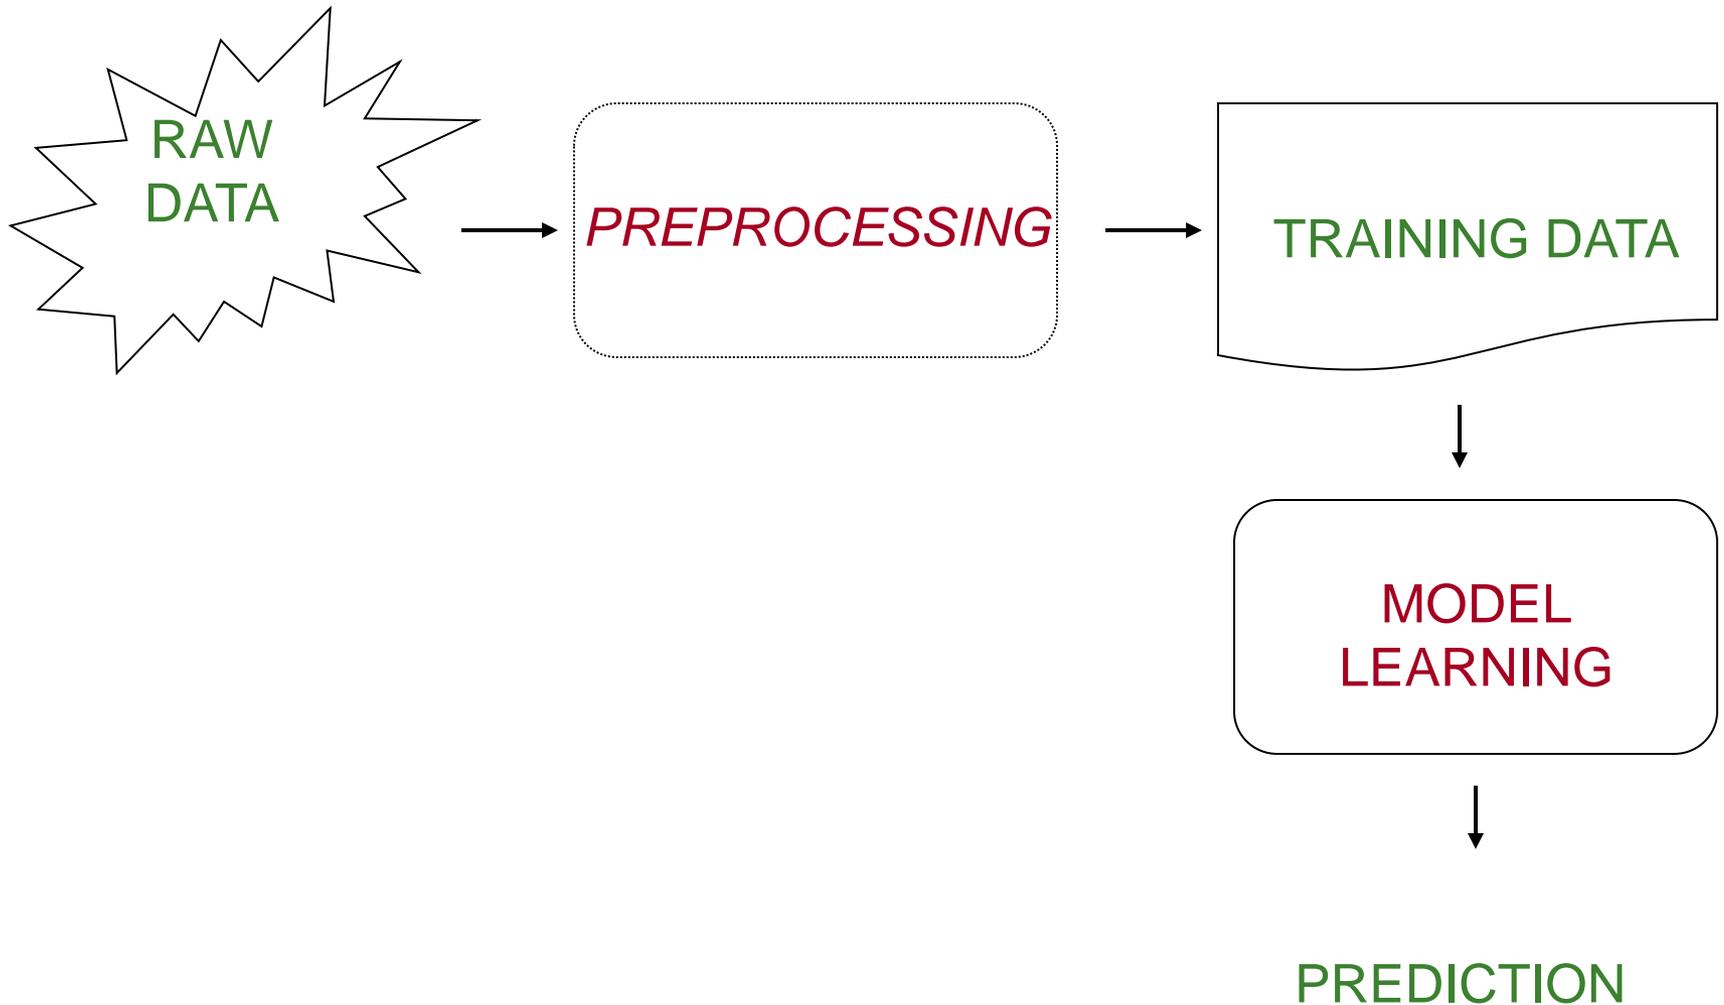

Building Models

A model needs data to exist but, once it exists, it can exist without the data

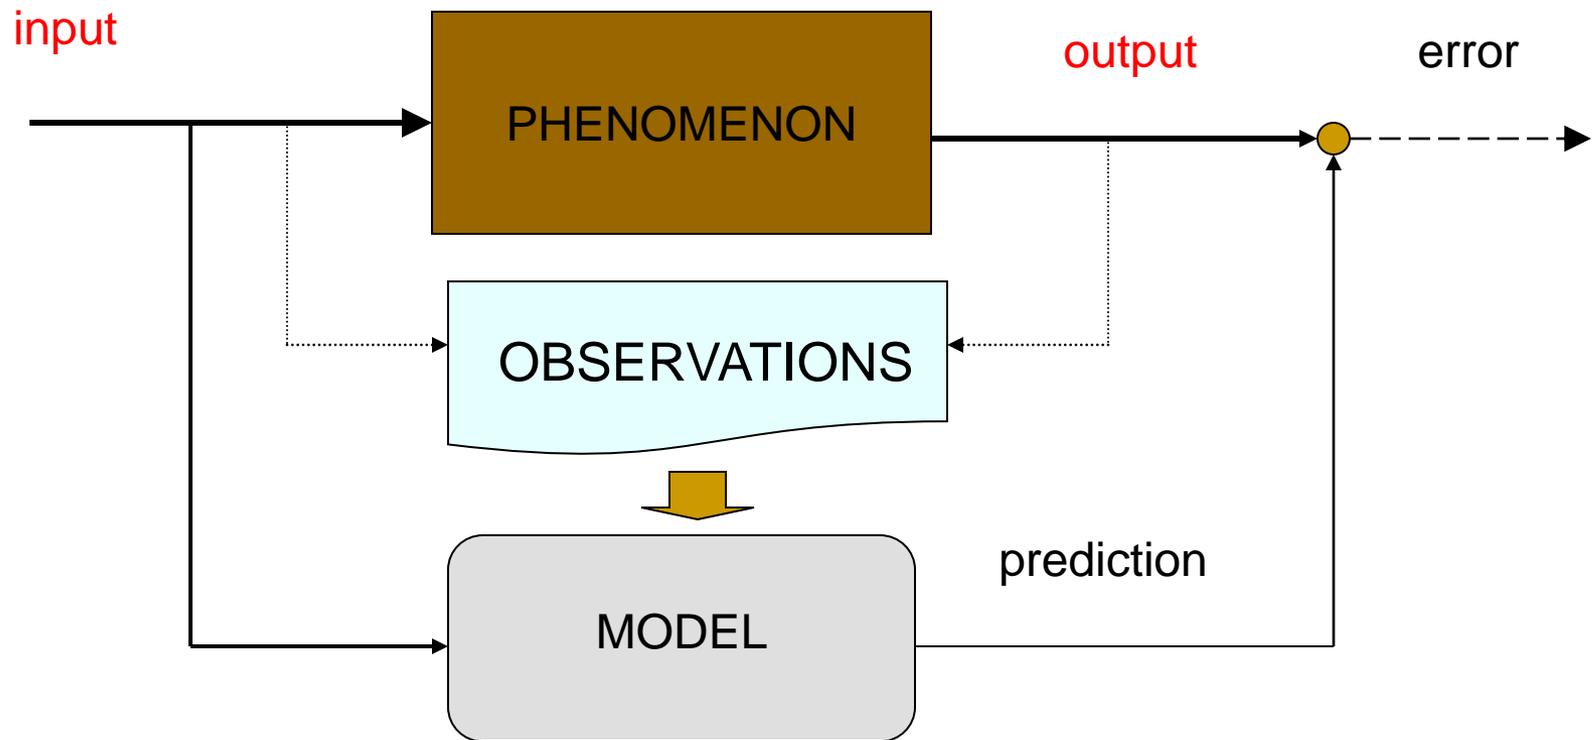

Linear, NN, Fuzzy, ID3, Wavelet, Fourier, Polynomes,...

From data to prediction

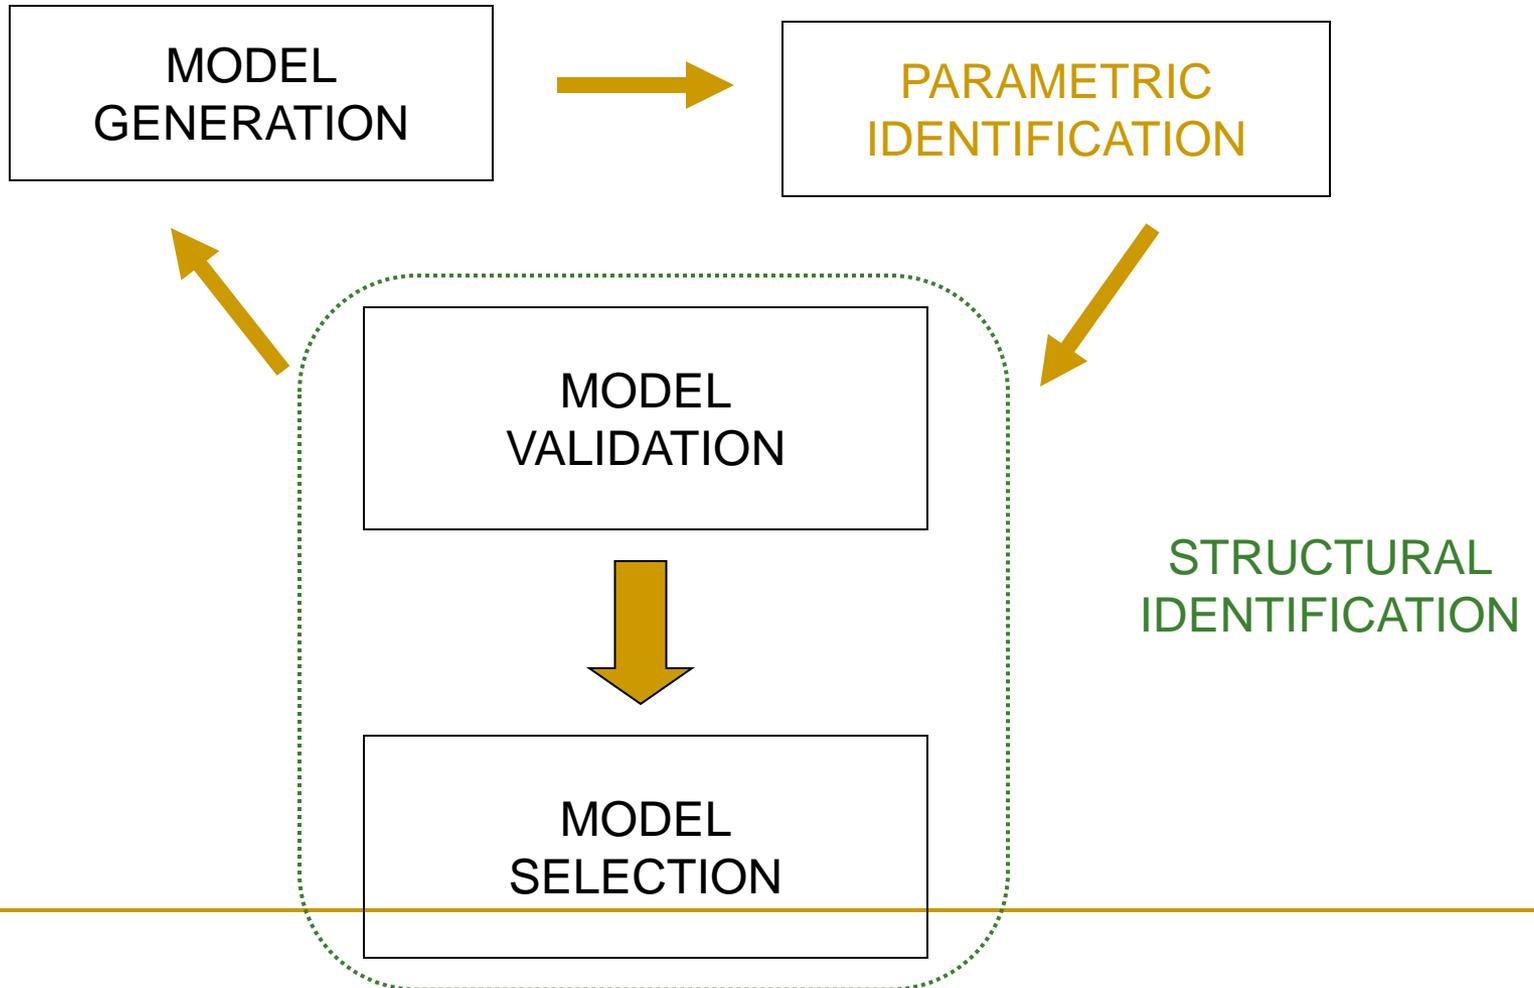

Supervised learning

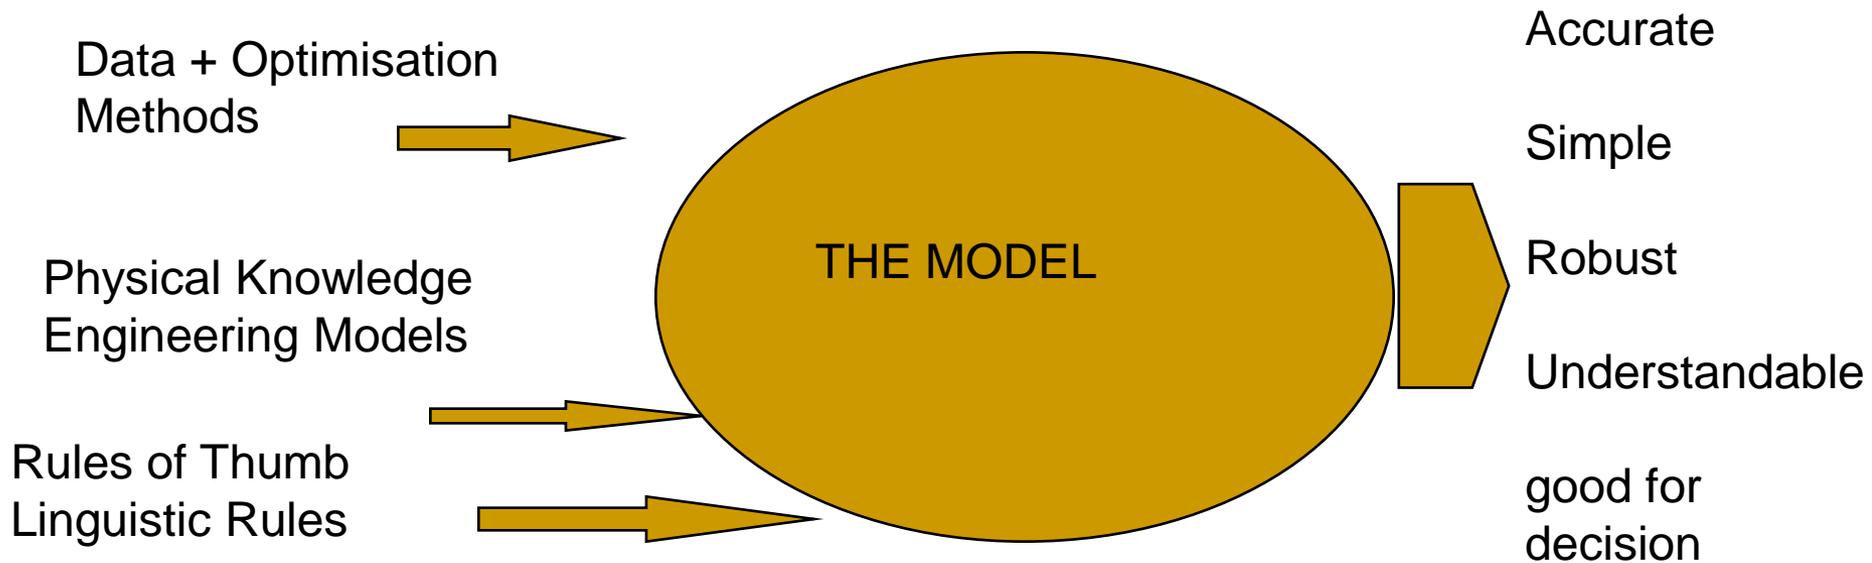

- **Finite** amount of **noisy** observations.
- **No a priori knowledge** of the phenomenon.

Model learning

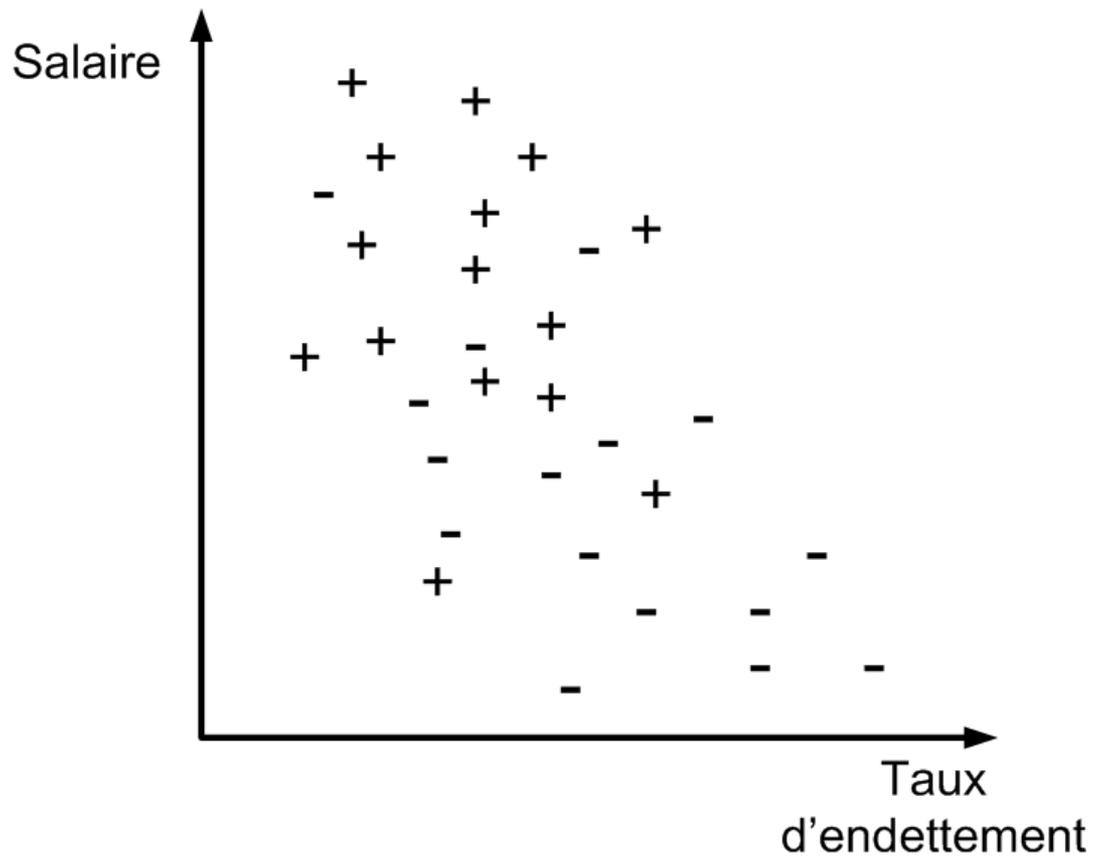

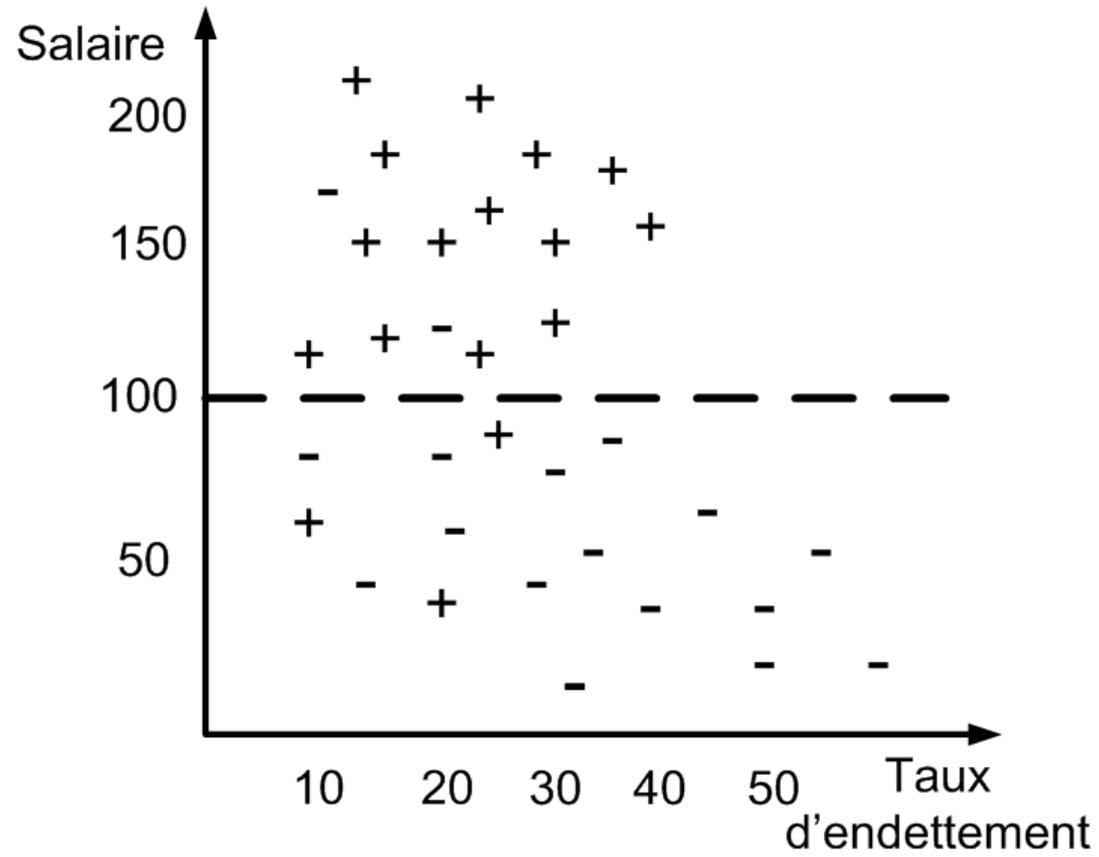

The Practice of Modelling

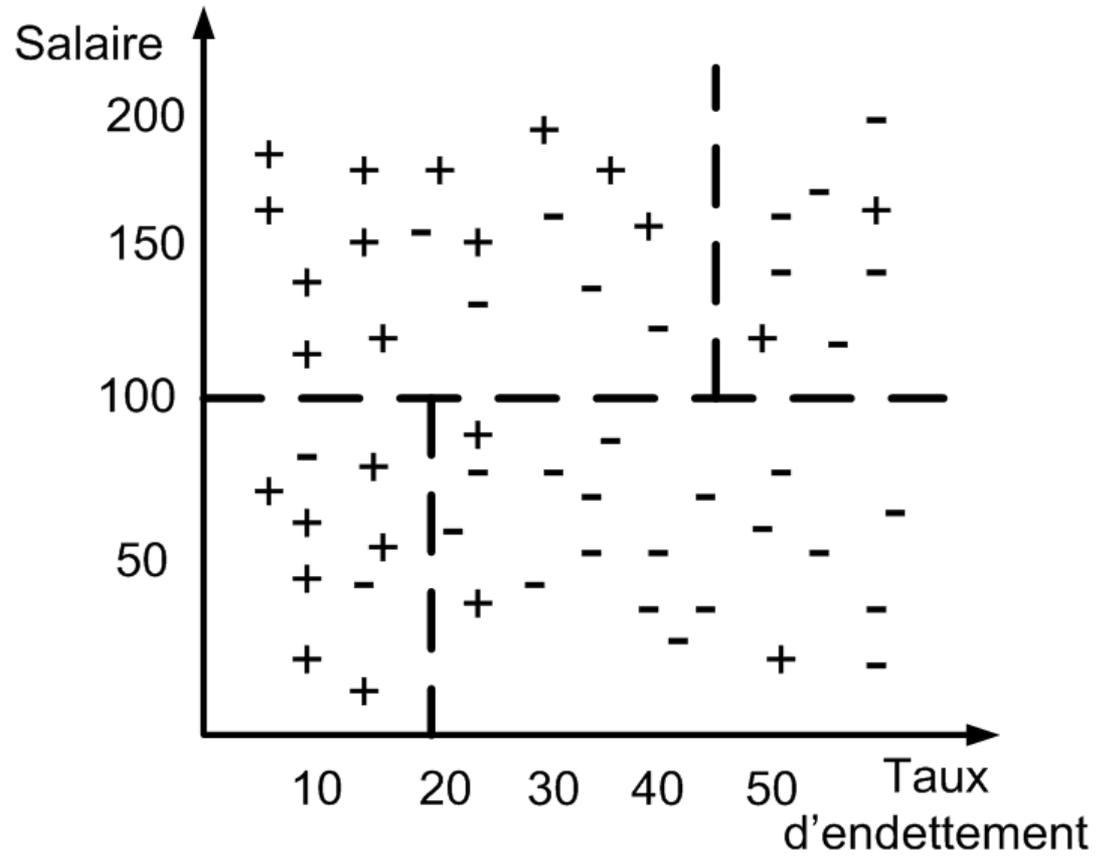

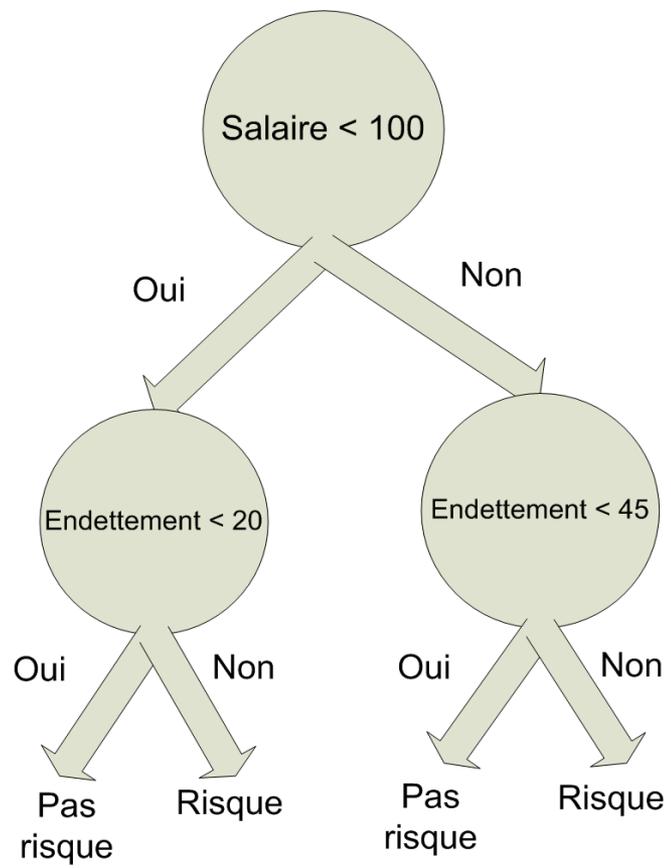

Comprehensible models

- **Decision trees**
 - Qualitative attributes
 - Force the attributes to be treated separately
 - classification surfaces parallel to the axes
 - good for comprehension because they select and separate the variables
-

Decision trees

- Very used in practice. One of the favorite data mining methods
 - Work with noisy data (statistical approaches) can learn logical model out of data expressed by and/or rules
 - ID3, C4.5 ---> Quinlan
 - Favoring little trees --> simple models
-

-
- At every stage the most discriminant attribute
 - The tree is being constructed top-down adding a new attribute at each level
 - The choice of the attribute is based on a statistical criteria called : “the information gain”
 - Entropie = $-p_{oui} \log_2 p_{oui} - p_{non} \log_2 p_{non}$
 - Entropie = 0 if $P_{oui/non} = 1$
 - Entropie = 1 if $P_{oui/non} = 1/2$
-

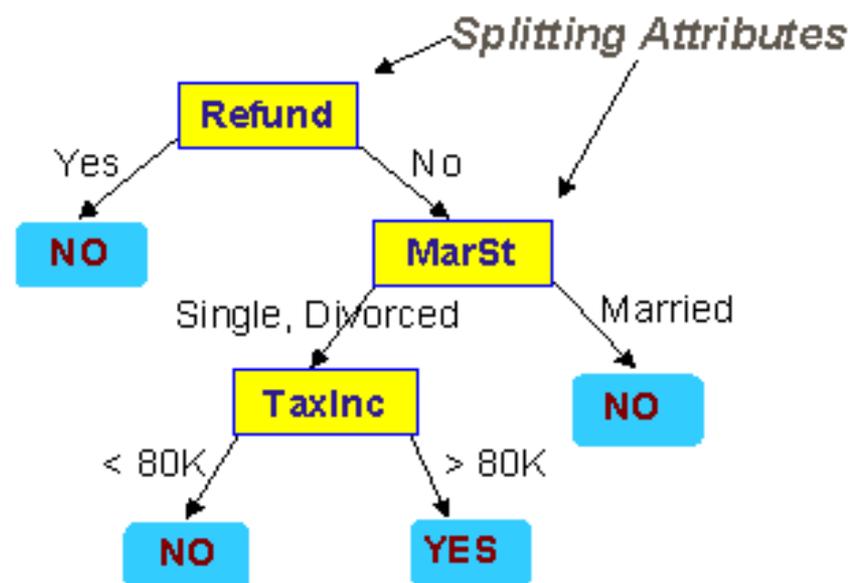

Information gain

- S = set of instances, A set of attributes and v set of values of attributes A
 - $\text{Gain}(S,A) = \text{Entropie}(S) - \sum_v |S_v|/|S| * \text{Entropie}(S_v)$
 - the best A is the one that maximises the Gain
 - The algorithm runs in a recursive way
 - The same mechanism is reapplied at each level
-

Example Decision Tree

categorical
categorical
continuous
class

| Tid | Refund | Marital Status | Taxable Income | Cheat |
|-----|--------|----------------|----------------|-------|
| 1 | Yes | Single | 125K | No |
| 2 | No | Married | 100K | No |
| 3 | No | Single | 70K | No |
| 4 | Yes | Married | 120K | No |
| 5 | No | Divorced | 95K | Yes |
| 6 | No | Married | 60K | No |
| 7 | Yes | Divorced | 220K | No |
| 8 | No | Single | 85K | Yes |
| 9 | No | Married | 75K | No |
| 10 | No | Single | 90K | Yes |

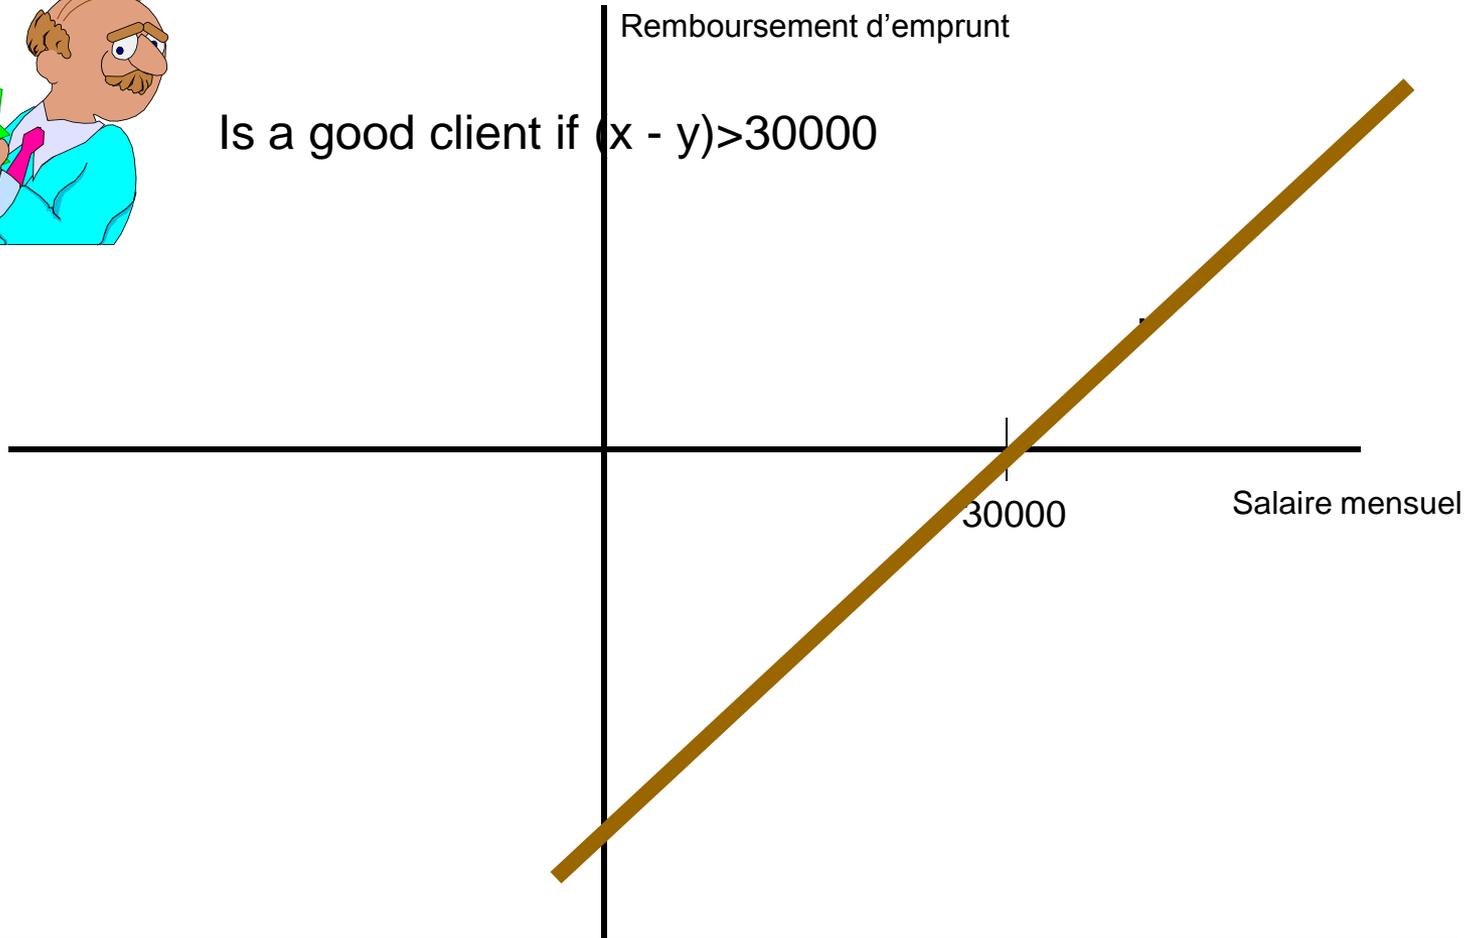

The splitting attribute at a node is determined based on the Gini index.

BUT !!!!

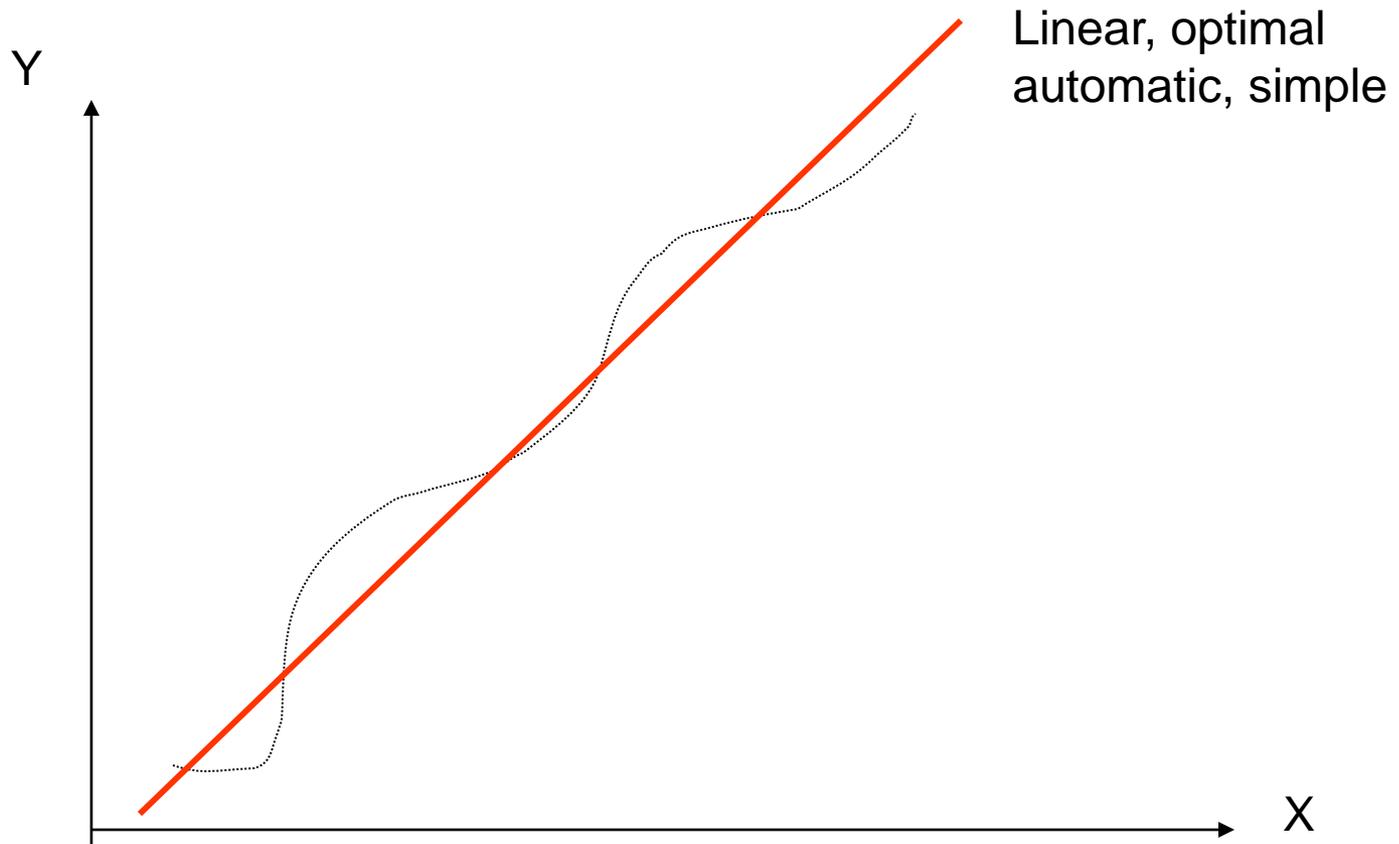

Is a good client if $(x - y) > 30000$

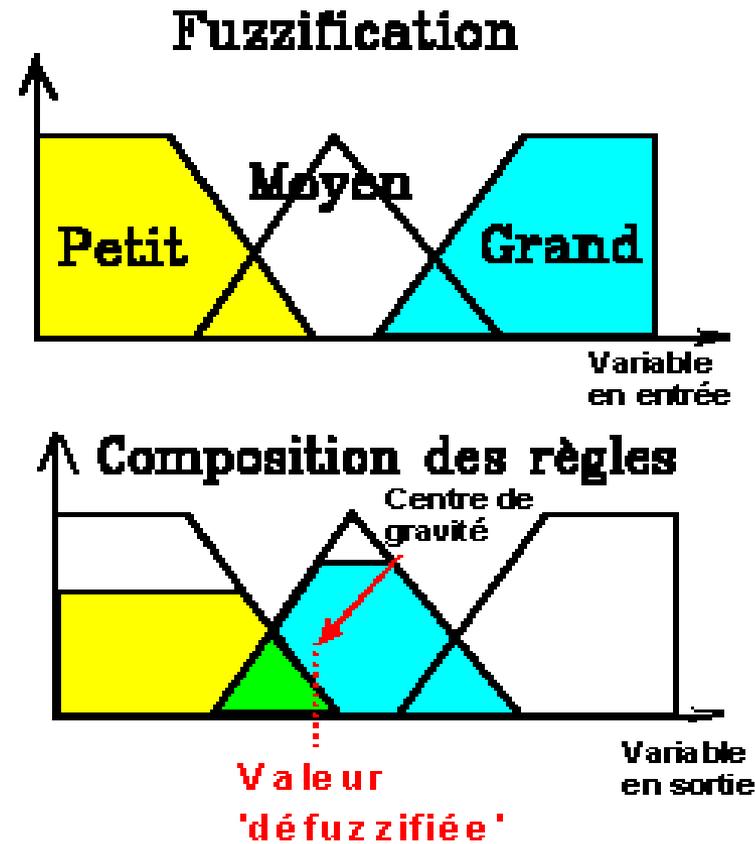

Other comprehensible models

- Fuzzy logic
- Realize an I/O mapping with linguistic rules
- If I eat “a lot” then I take weight “a lot”

Trivial example

The fuzzy

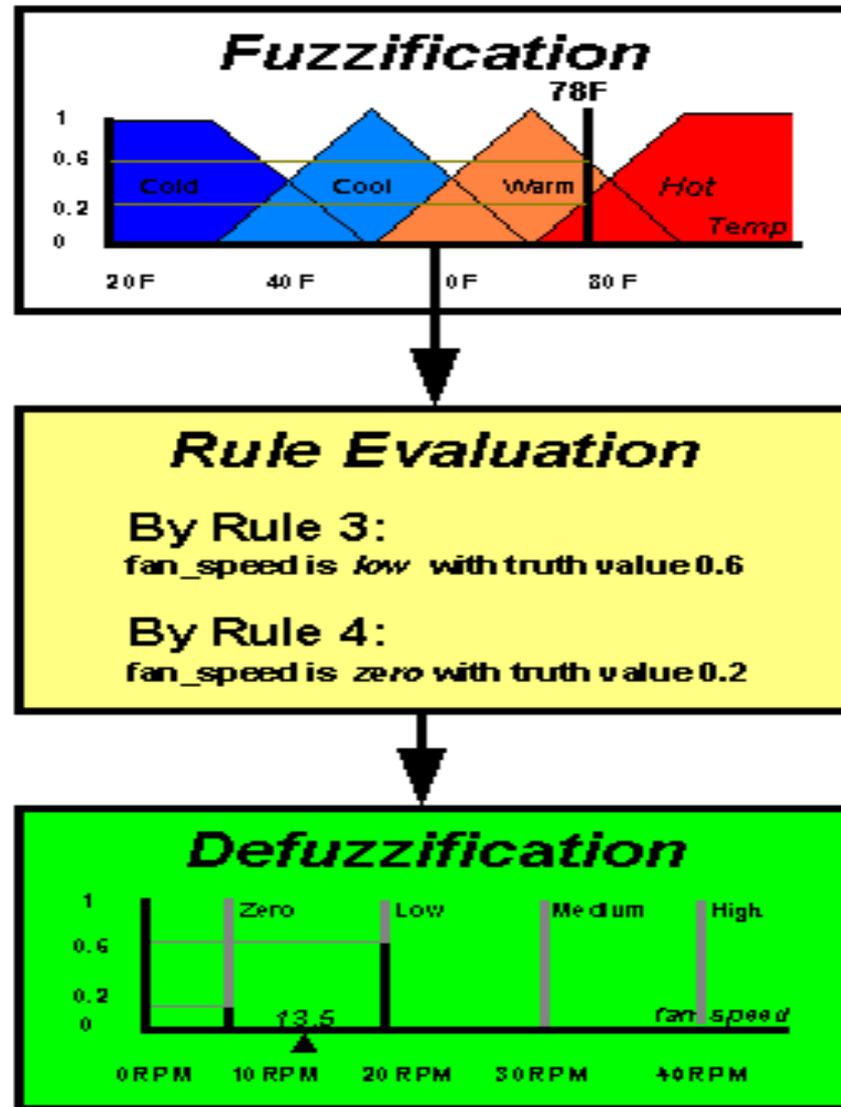

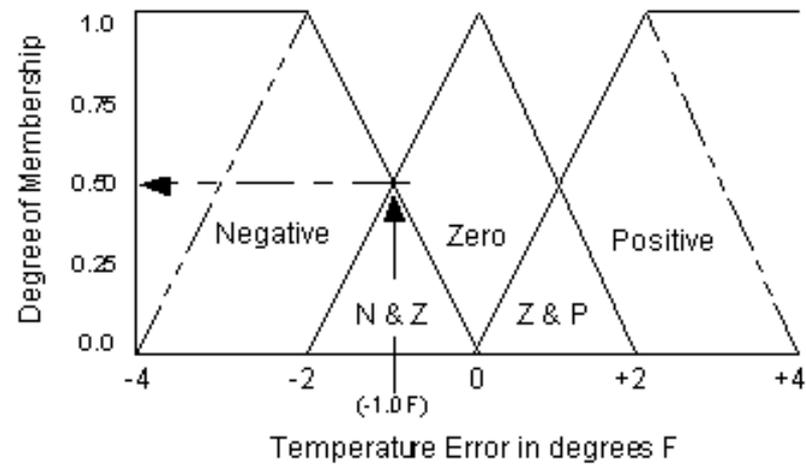

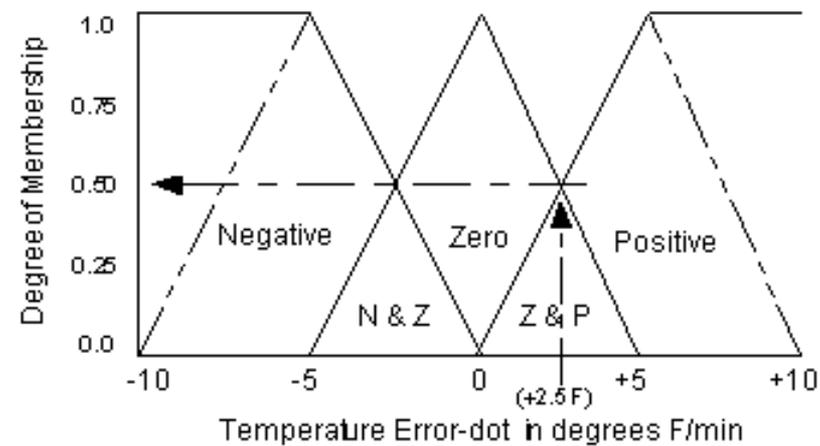

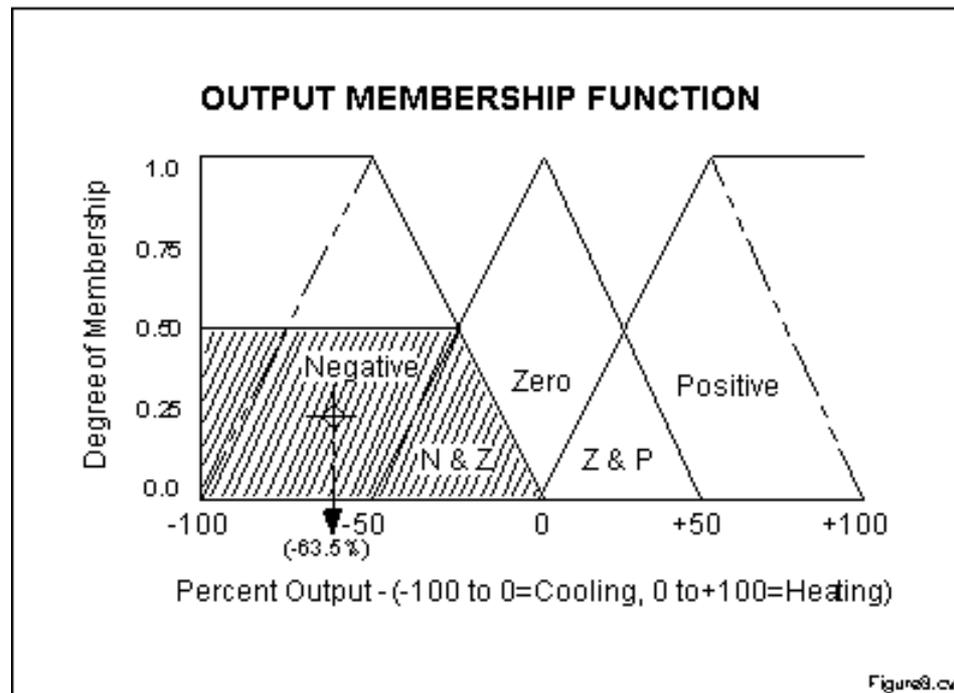

Figure 3 The Fuzzy Inference Process

ERROR MEMBERSHIP FUNCTION

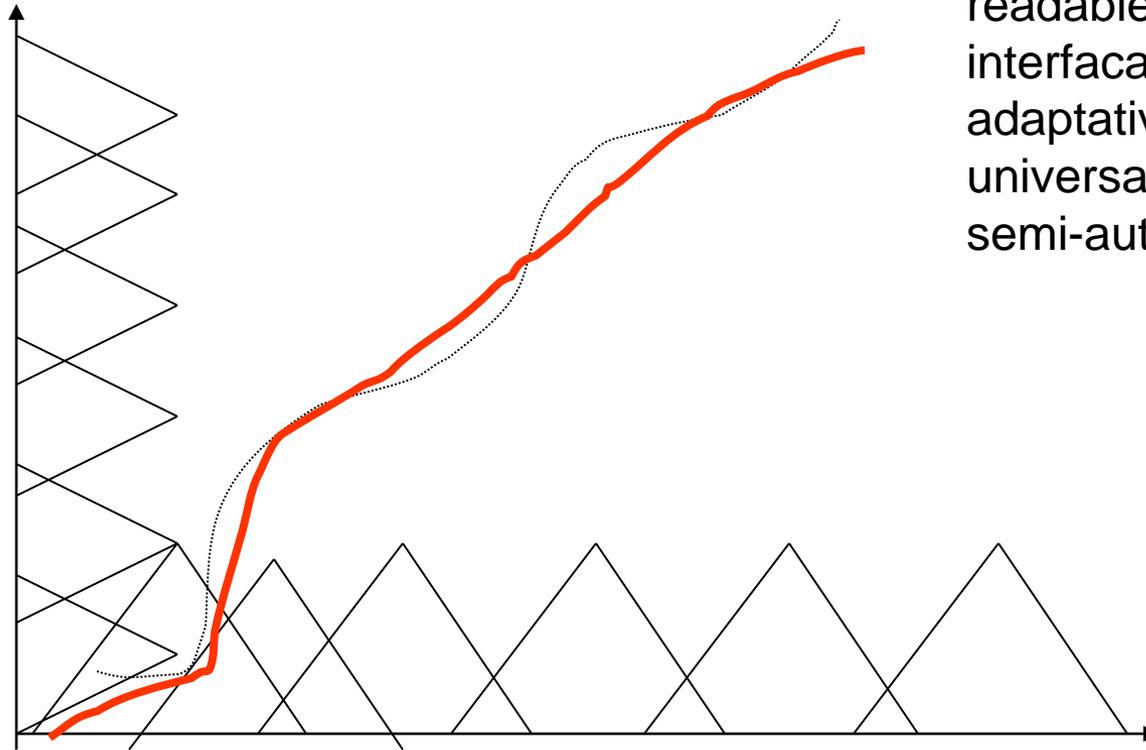

ERROR-DOT MEMBERSHIP FUNCTION

IF x is very small THEN y is small
IF x is small THEN y is medium
IF x is medium THEN y is medium

Y

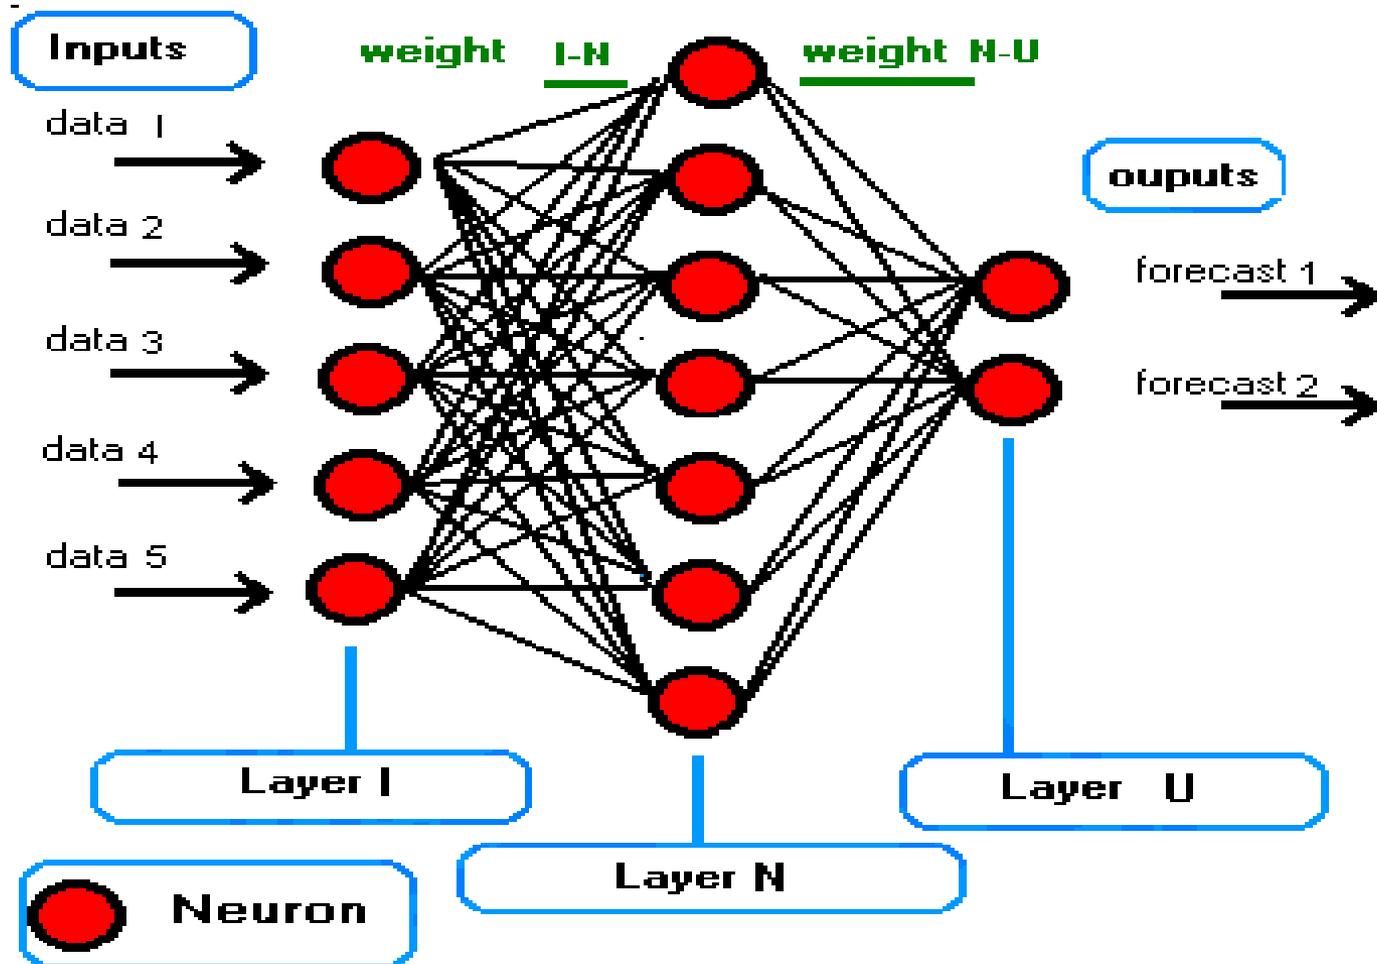

readable ?
interfacable ?
adaptative
universal
semi-automatic

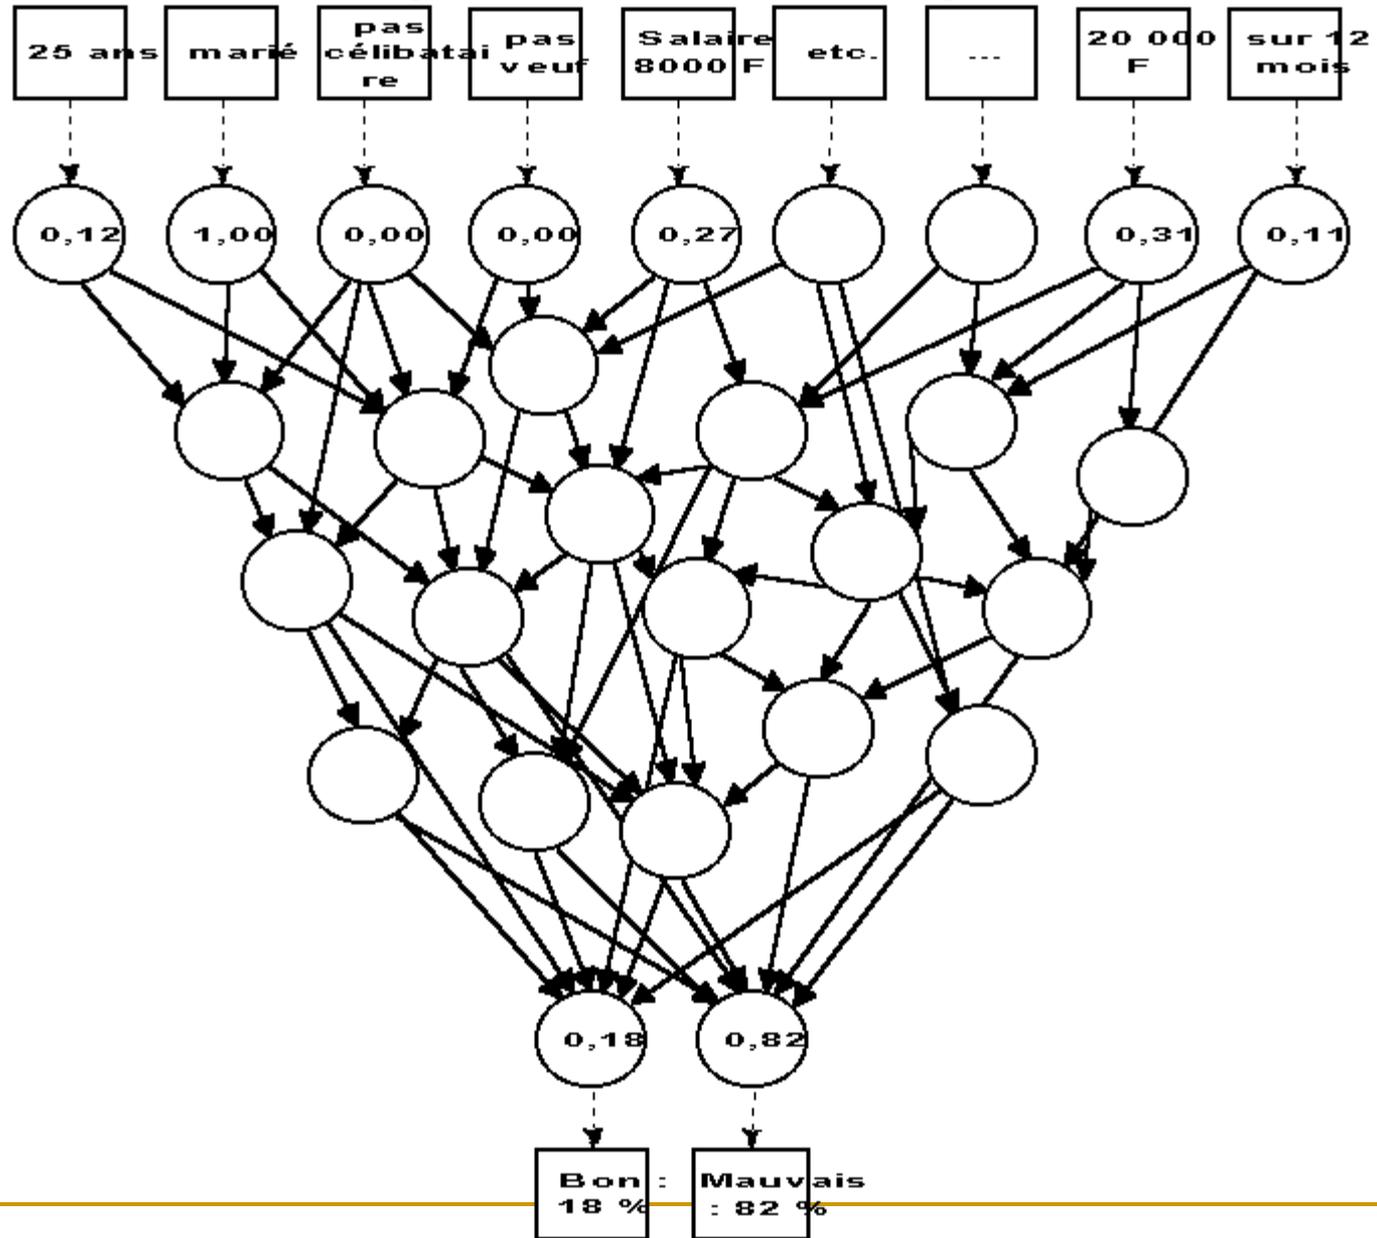

Non comprehensible models

- From more to less
 - linear discriminant
 - local approaches
 - fuzzy rules
 - Support Vector Machine
 - RBF
 - global approaches
 - NN
 - polynômes, wavelet,...
 - Support Vector Machine
-

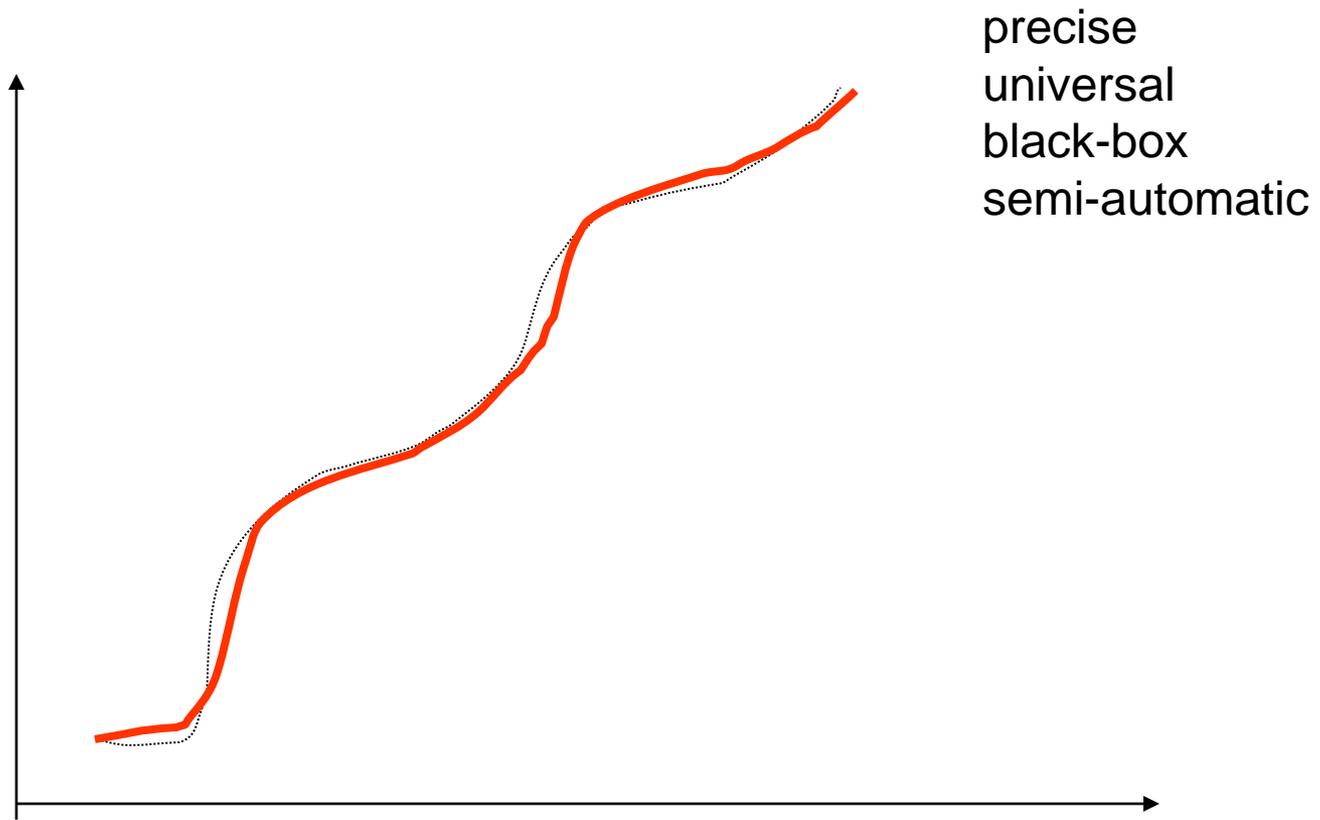

The neural network

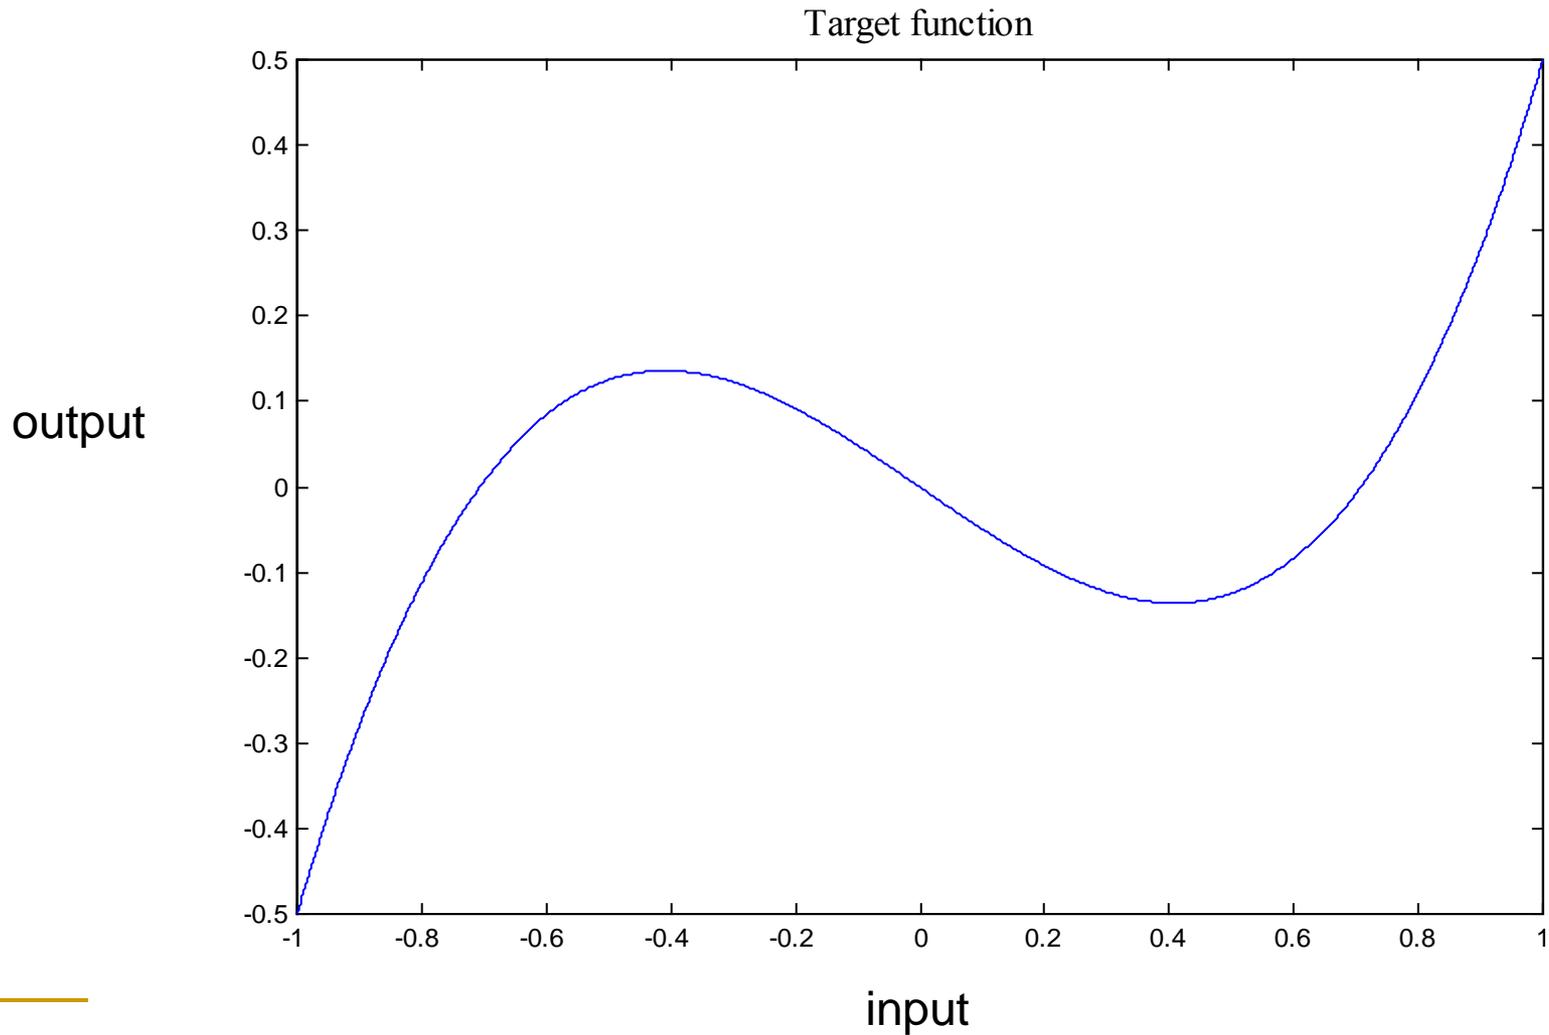

description de dossier de prêt

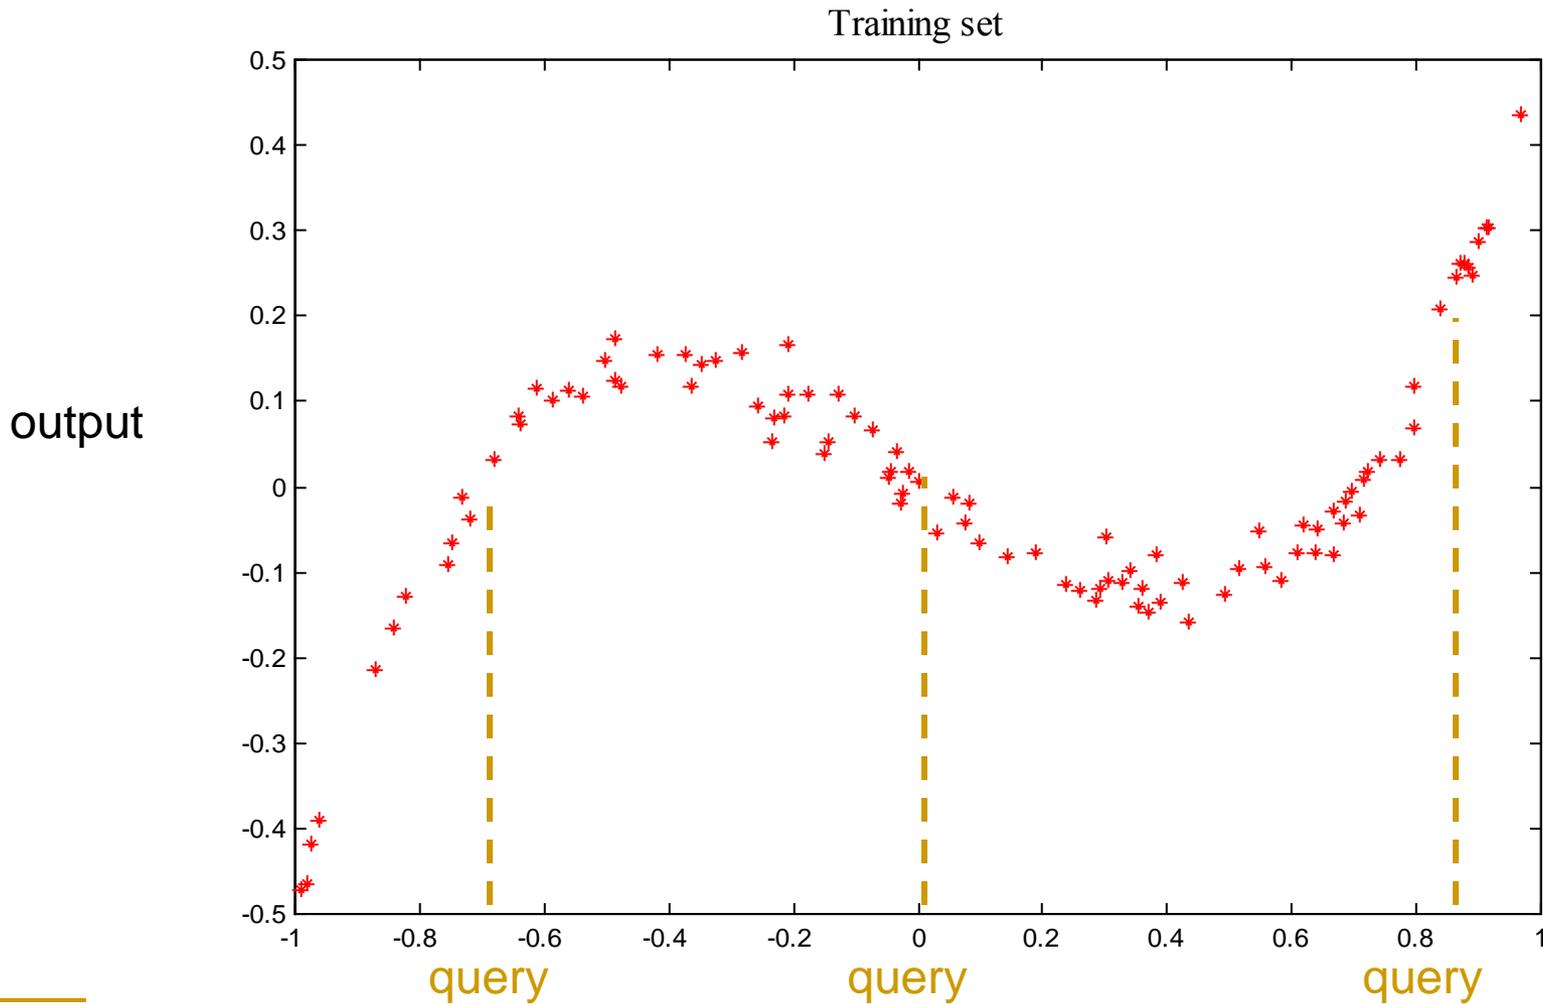

suggestion de décision

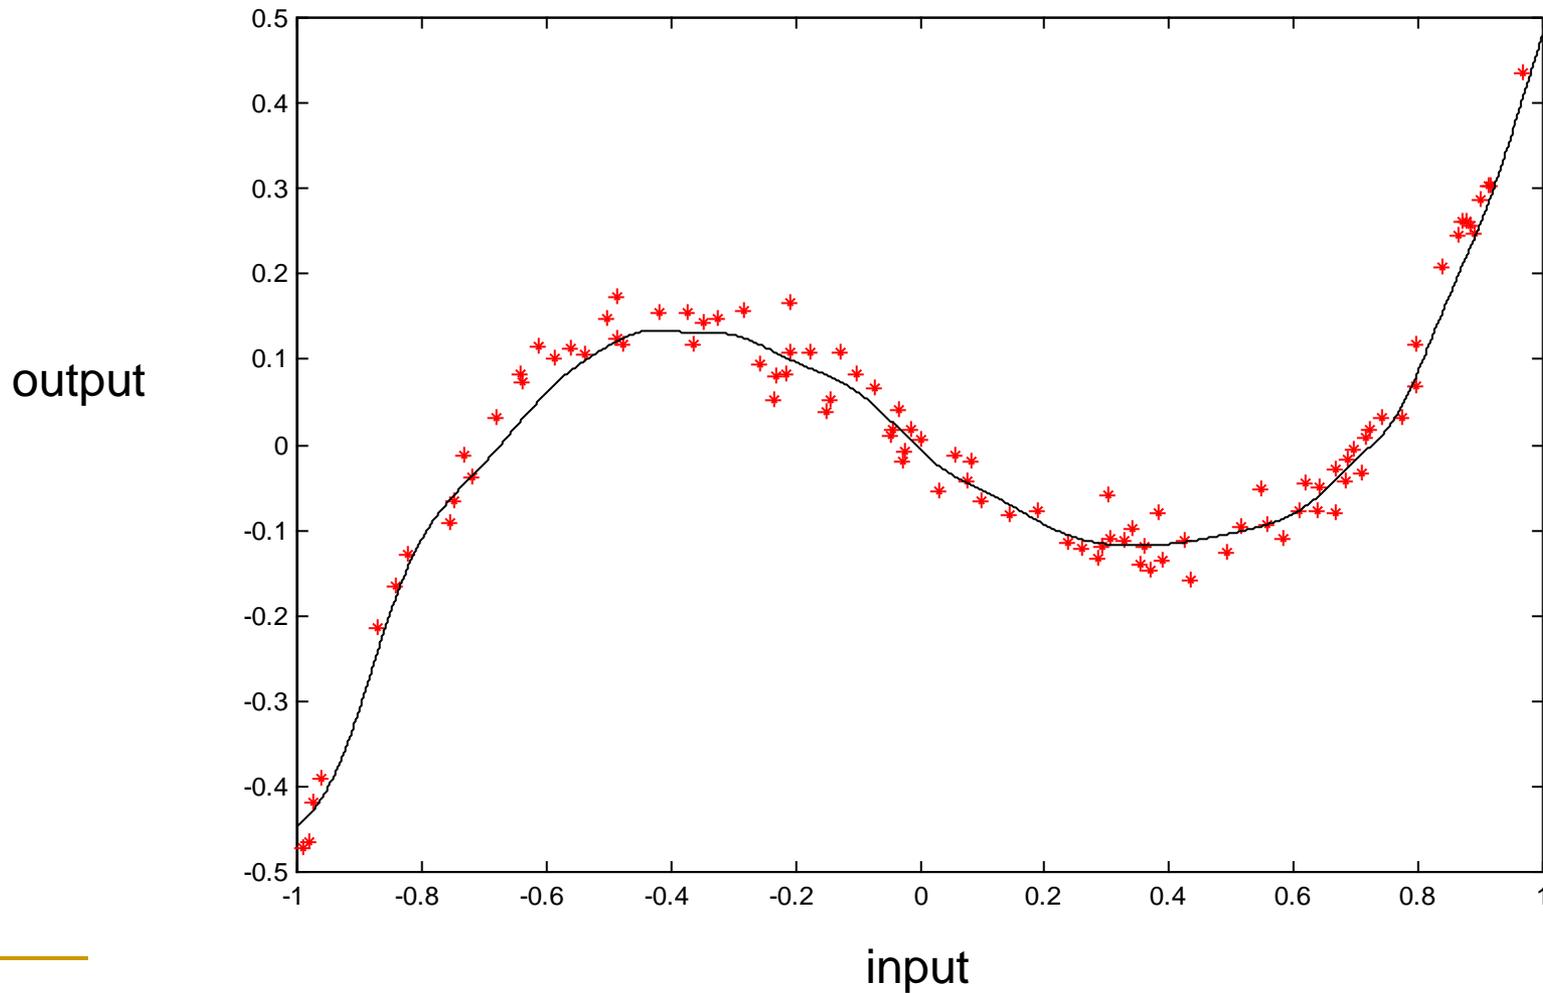

Nonlinear relationship

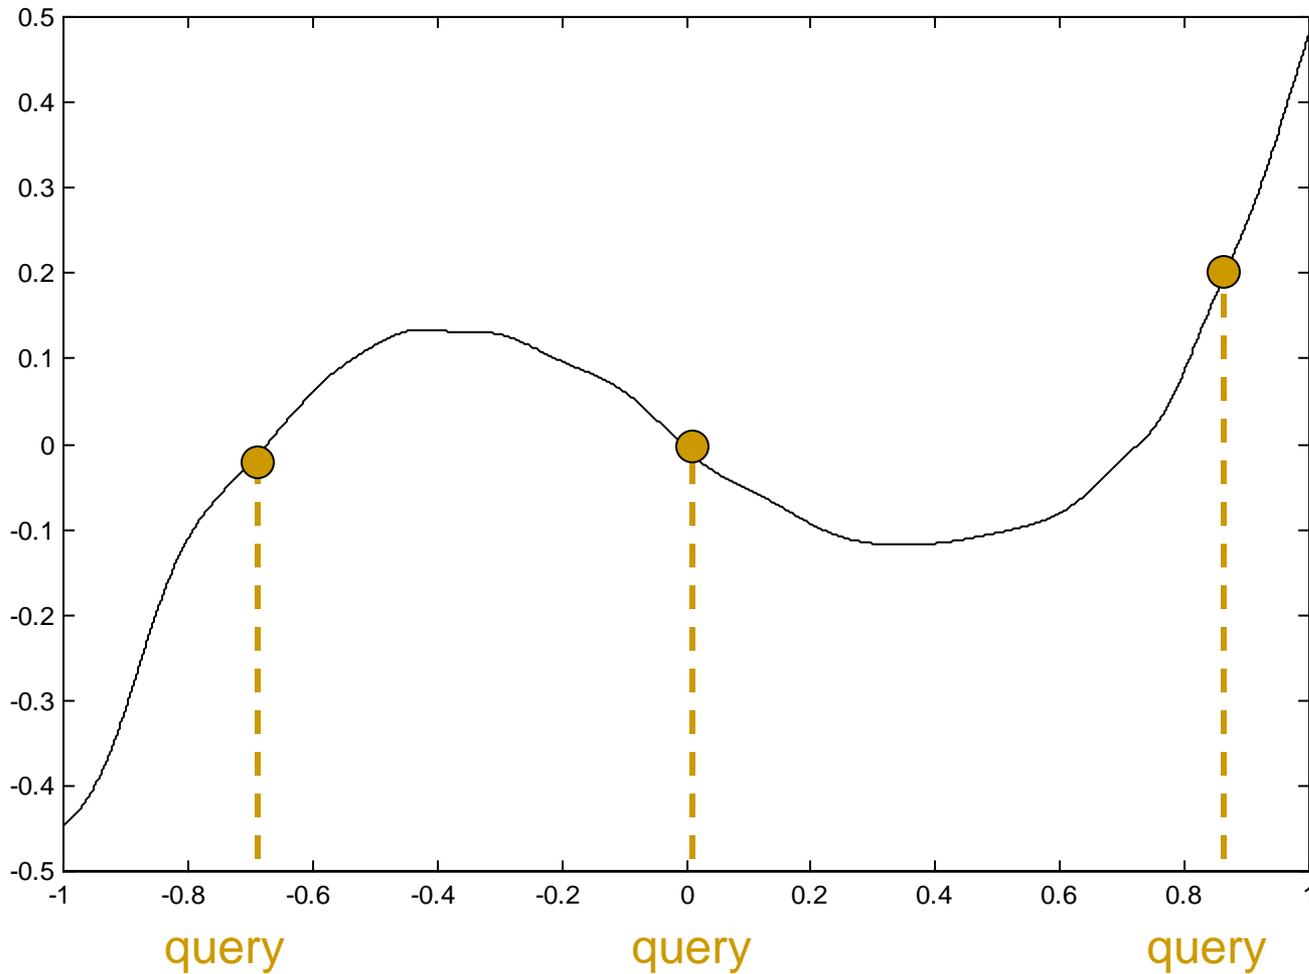

Observations

Global modeling

Prediction with global models

Advantages

- Exist without data
 - Information compression
 - Mainly SVM: mathématiques, pratiques, logique et génériques.
 - Detect a global structure in the data
 - Allow to test the sensitivity of the variables
 - Can easily incorporate prior knowledge
-

Drawbacks

- Make assumption of uniformity
 - Have the bias of their structure
 - Are hardly adapting
 - Which one to choose.
-

BAGFS: ensemble method

'Weak classifiers' ensembles

- Classifier capacity reduced in 2 ways :
 - simplified internal architecture
 - NOT all the available information
 - Better **generalisation**, reducing **overfitting**
 - Improving **accuracy**
 - ☞ by **decorrelating** classifiers errors
 - ☞ by increasing the **variability** in the learning space.
-

`Bagging` : resampling the learning set

- Bootstraps aggregating (*Leo Breiman*)
 - random and independant perturbation of the learning set.
 - vital element : **instability** of the inducer*.
 - e.g. **C4.5**, **neural network** but not **kNN** !
 - increase **accuracy** by reducing **variance**

* inducer = base learning algorithm : c4.5, kNN, ...

Learning set resampling : `Arcing`

- **Adaptive** resampling or reweighting of the learning set (*Leo Breiman* terminology).
 - ☞ **Boosting** (*Freund & Schapire*)
 - sequential reweighting based on the description accuracy.
 - ☞ e.g. **AdaBoost.M1** for multi-class problems.
 - needs instability so as bagging
 - better variability than bagging.
 - sensible to noisy databases.
 - better than *bagging* on non-noisy databases
-

Multiple Feature Subsets :

Stephen D. Bay (1/2)

- problem ?
 - **kNN is stable vertically** so Bagging doesn't work.
 - ☞ **horizontally : MFS** - combining random selections of features with or without replacement.
 - question ?
 - what about other inducers such C4.5 ??
-

Multiple Feature Subsets :

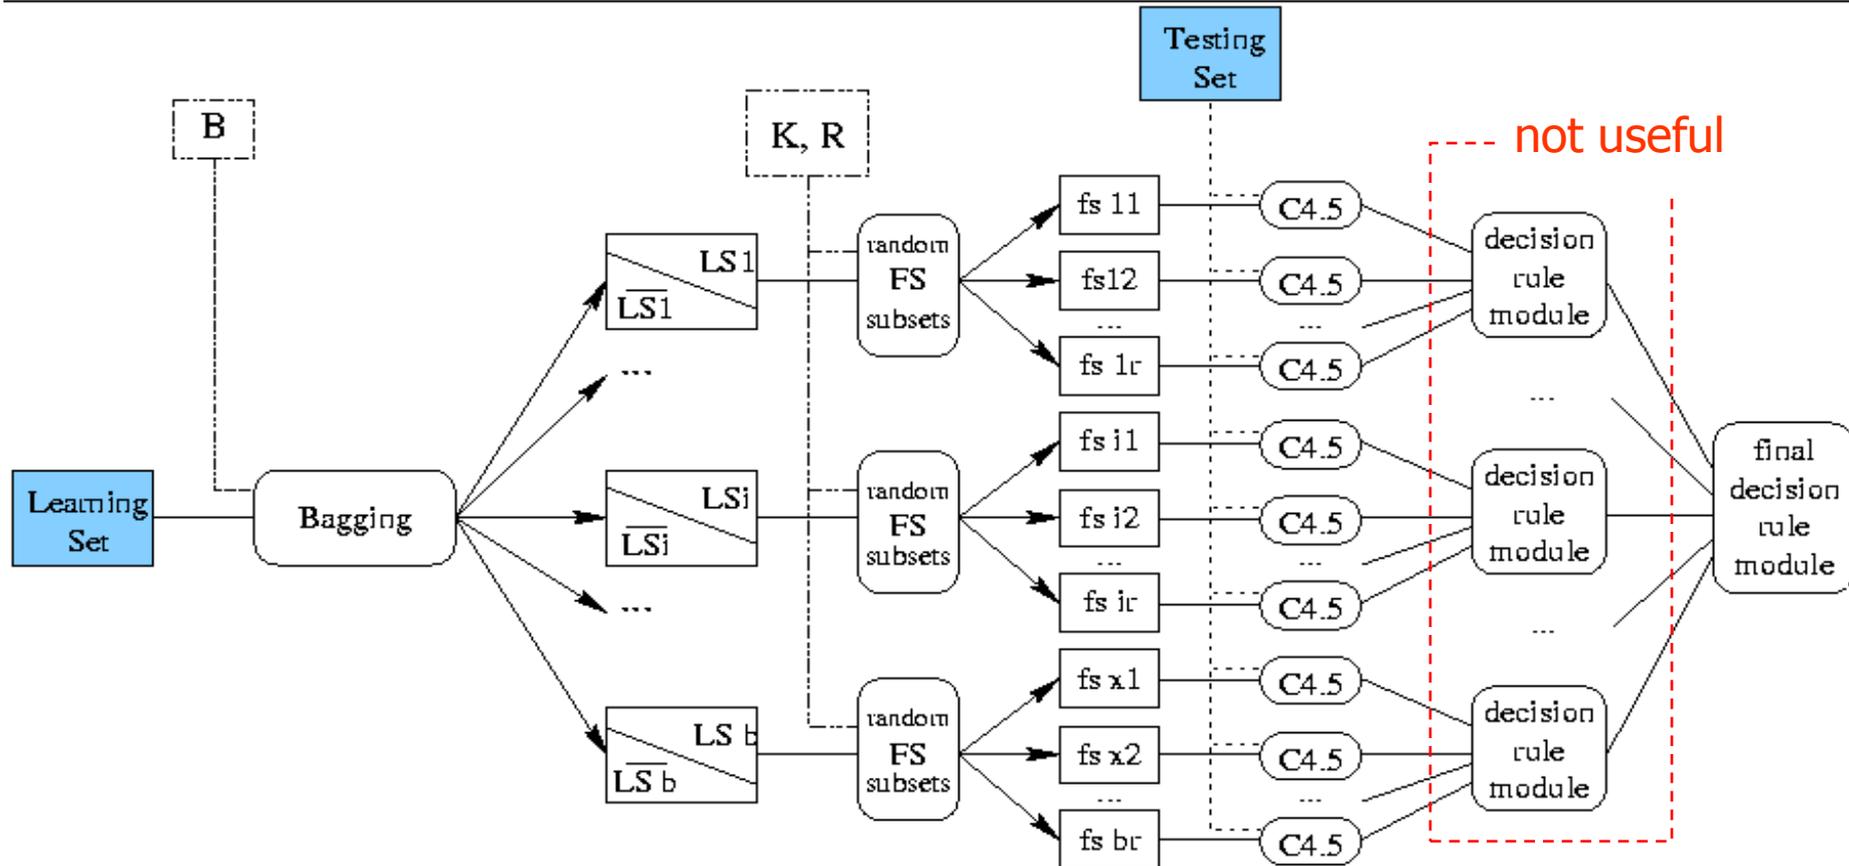

Stephen D. Bay (2/2)

- **Hypo** : kNN uses its ‘ horizontal ’ instability.
 - Two parameters :
 - $K=n/N$, proportion of features in subsets.
 - R , number of subsets to combine.
 - ☺ MFS is better than single kNN with FSS and BSS, feature selections techniques.
 - ☺ MFS is **more stable** than kNN on added irrelevant features.
 - ☺ MFS **decreases** variance and bias through randomness.
-

BAGFS : a multiple classifier system

- BAGFS = MFS inside each Bagging.
 - BAGMFS = MFS & Bagging together.
 - 3 parameters
 - **B**, number of bootstraps
 - **K**= n/N , proportion of features in subsets
 - **R**, number of feature subsets
 - decision rule : majority vote
-

BAGFS architecture around C4.5

Experiments

- Testing parametrization
 - optimizing K between 0.1 and 1 by means of a nested 10-fold cross-validation
 - $R=7, B=7$ for two-level method : Bagfs 7x7
 - set of 50 classifiers otherwise : Bag 50, BagMfs 50, MFS 50, Boosting 50

Experimental Results

| | c45 | bagmfs 50 | bagfs 7x7 | boosting 50 | bag 50 | mfs 50 |
|------------------------|------|-------------|-------------|-------------|-------------|-------------|
| hepatitis | 77.6 | 82.7 | 84.1 | 82.1 | 81.0 | 83.2 |
| glass | 64.8 | 77.3 | 76.6 | 74.4 | 74.8 | 75.2 |

| Image | 96.5 | 97.3 | 97.8 | 96.7 | 97.6 | 97.6 |
| car | 92.1 | 93.2 | 92.5 | 92.1 | 93.2 | 92.2 |
| diabetes | 72.4 | 75.7 | 75.7 | 76.2 | 75.7 | 74.0 |
| | 84.8 | 90.0 | 89.6 | 88.8 | 89.0 | 88.9 |

- McNemar test of significance (95%) : Bagfs performs never signif. worse and even sign. better on at least 4 databases (see red databases).

BAGFS : discussions

- **How adjusting the parameters B, K, R**
 - internal cross validation ?
 - dimensionality and variability measures *hypothesis*
 - **Interest of a second level ?**
 - About irrelevant and (un)informative features ?
 - Does bagging + feature selections work better ?
 - How proving the interest of MFS randomness ?
 - **How using bootstraps complementary ?**
 - Can we ?
 - What to do ?
 - **How proving horizontal unstability of C4.5 ?**
 - **Comparison with 1-level bagging and MFS**
 - Same number of classifiers ?
 - Advantage of tuning parameters ?
-

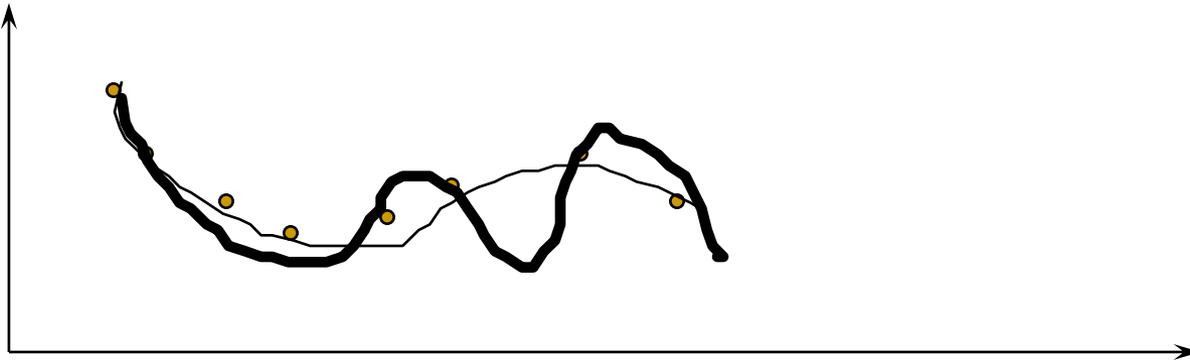

Which best model ??

when they all can perfectly fit the data

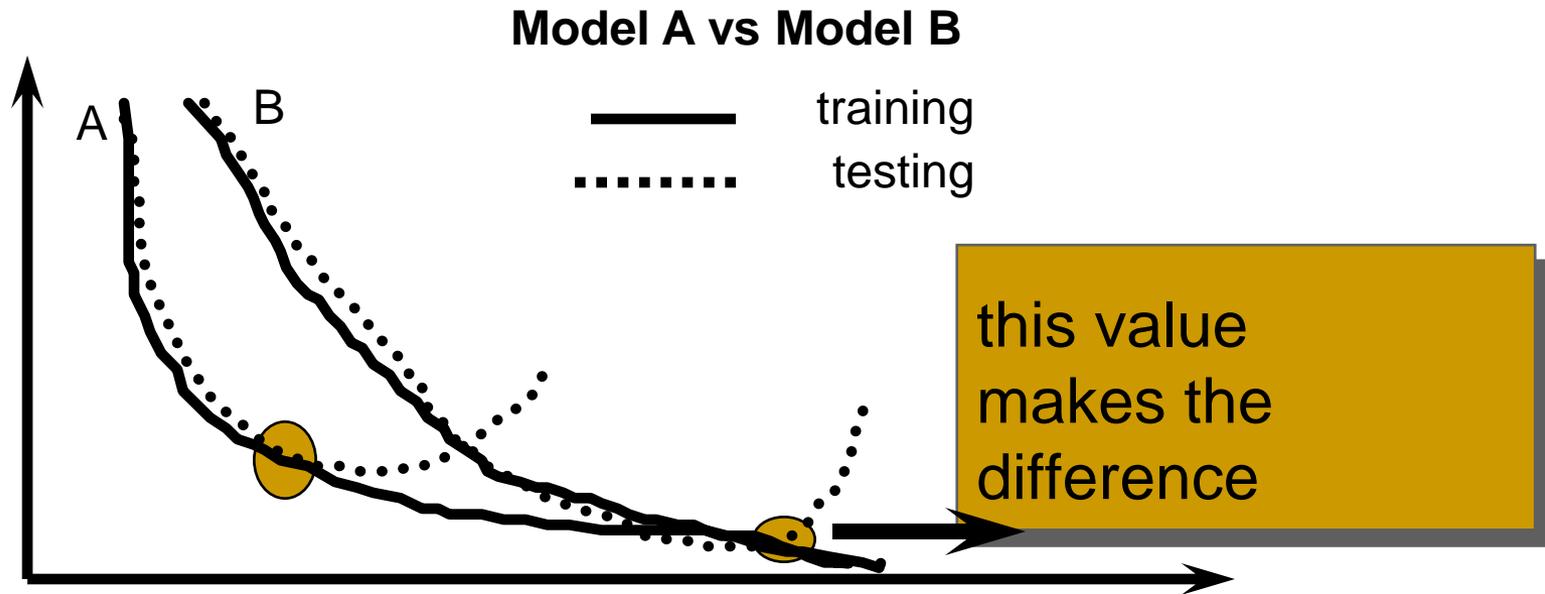

They all can perfectly fit the data but

they don't approach the data in the same way. This approach depends on their structure

This explains the importance of Cross-validation

Which one to choose

- Capital role of crossvalidation.
- Hard to run
- One possible response

-
- Lazy methods
 - Coming from fuzzy
-

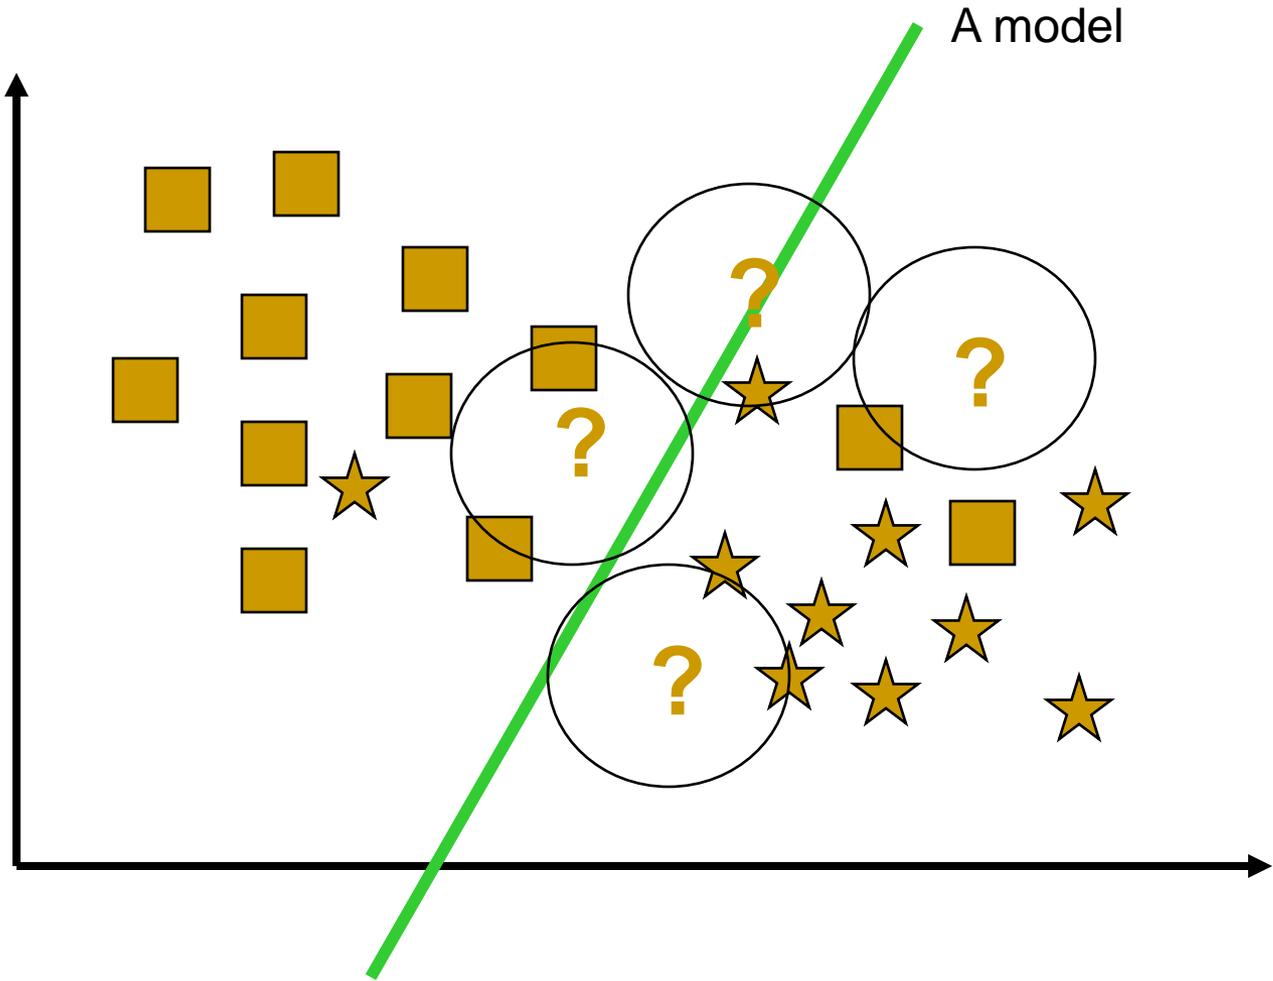

Model or Examples ??

Build a Model

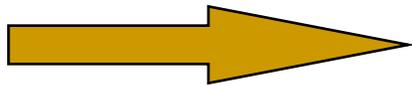

Prediction
based on the model

Prediction based
on the examples

Lazy Methods

- Accuracy entails to keep the data and don't use any intermediary model: the best model is the data
- Accuracy requires powerful **local** models with **powerful cross-validation methods**

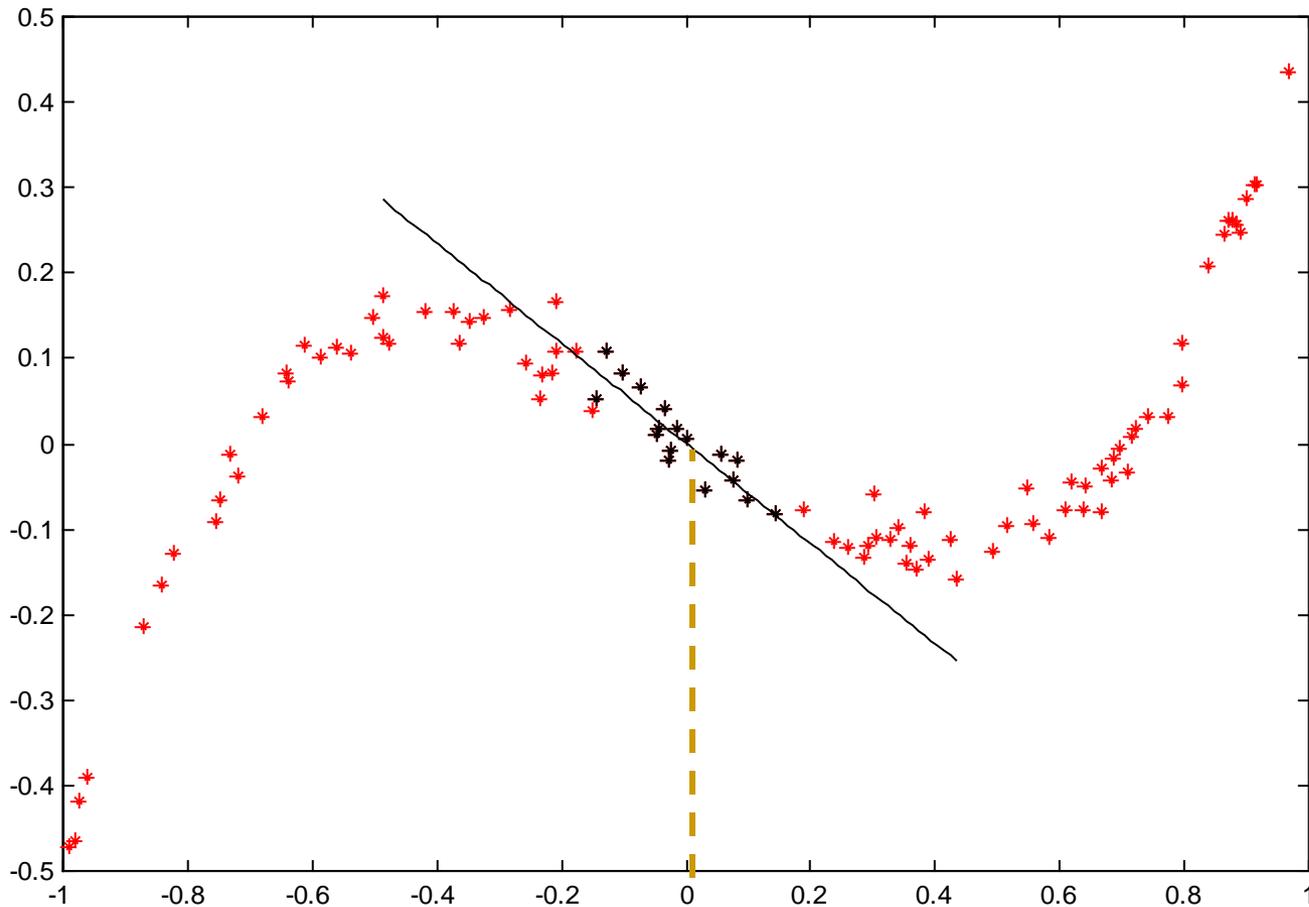

lazy methods is a new trend which is a revival of an old trend

- Made possible again due to the computer power

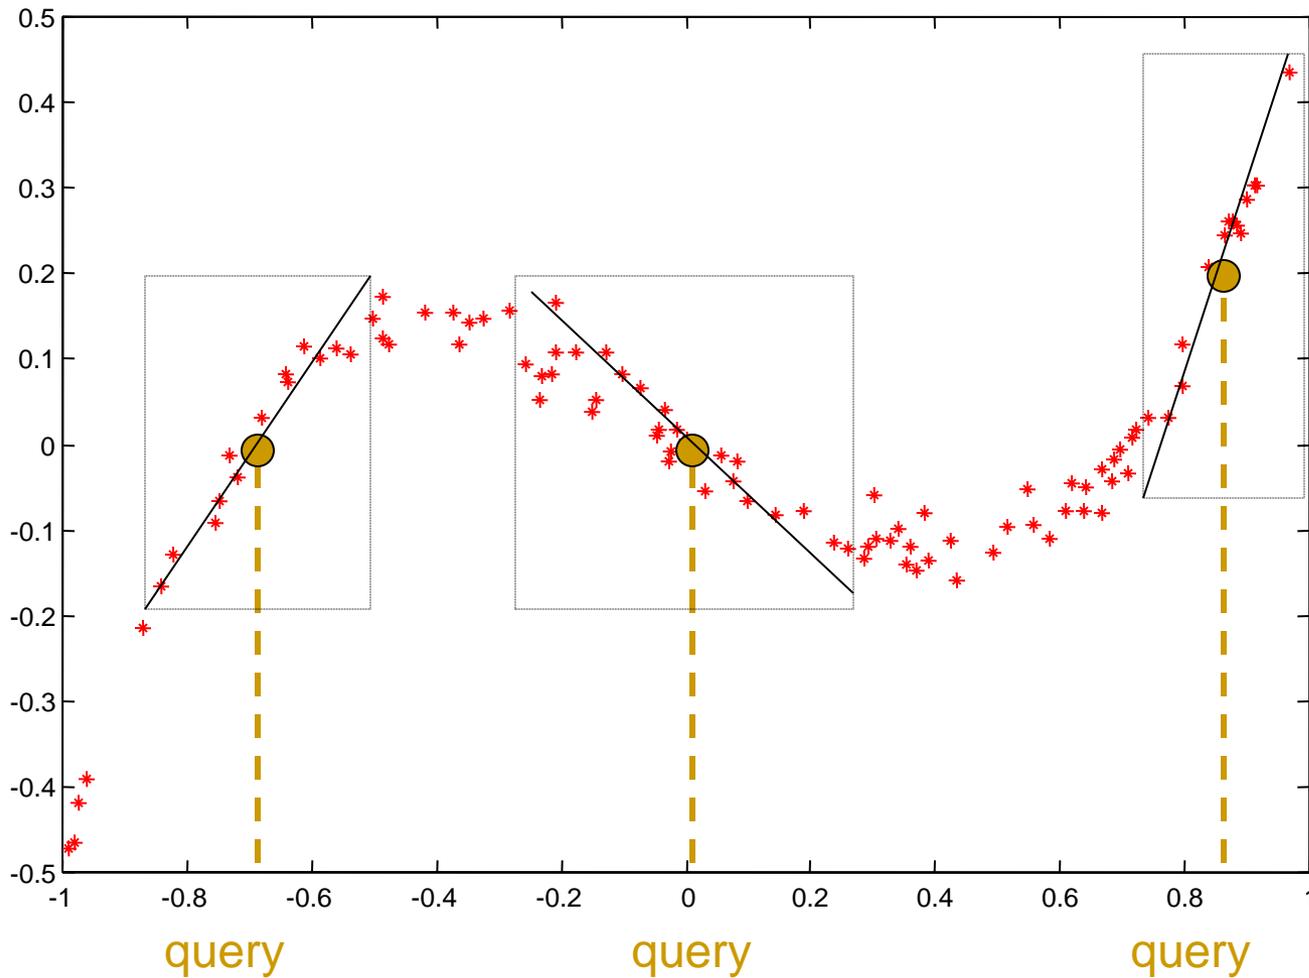

Lazy methods

- A lot of expressions for the same thing:
 - memory-based, instance-based, examples-based, distance-based
 - nearest-neighbour
 - lazy for regression, classification and time series prediction
 - lazy for quantitative and qualitative features
-

Local modeling

Prediction with local models

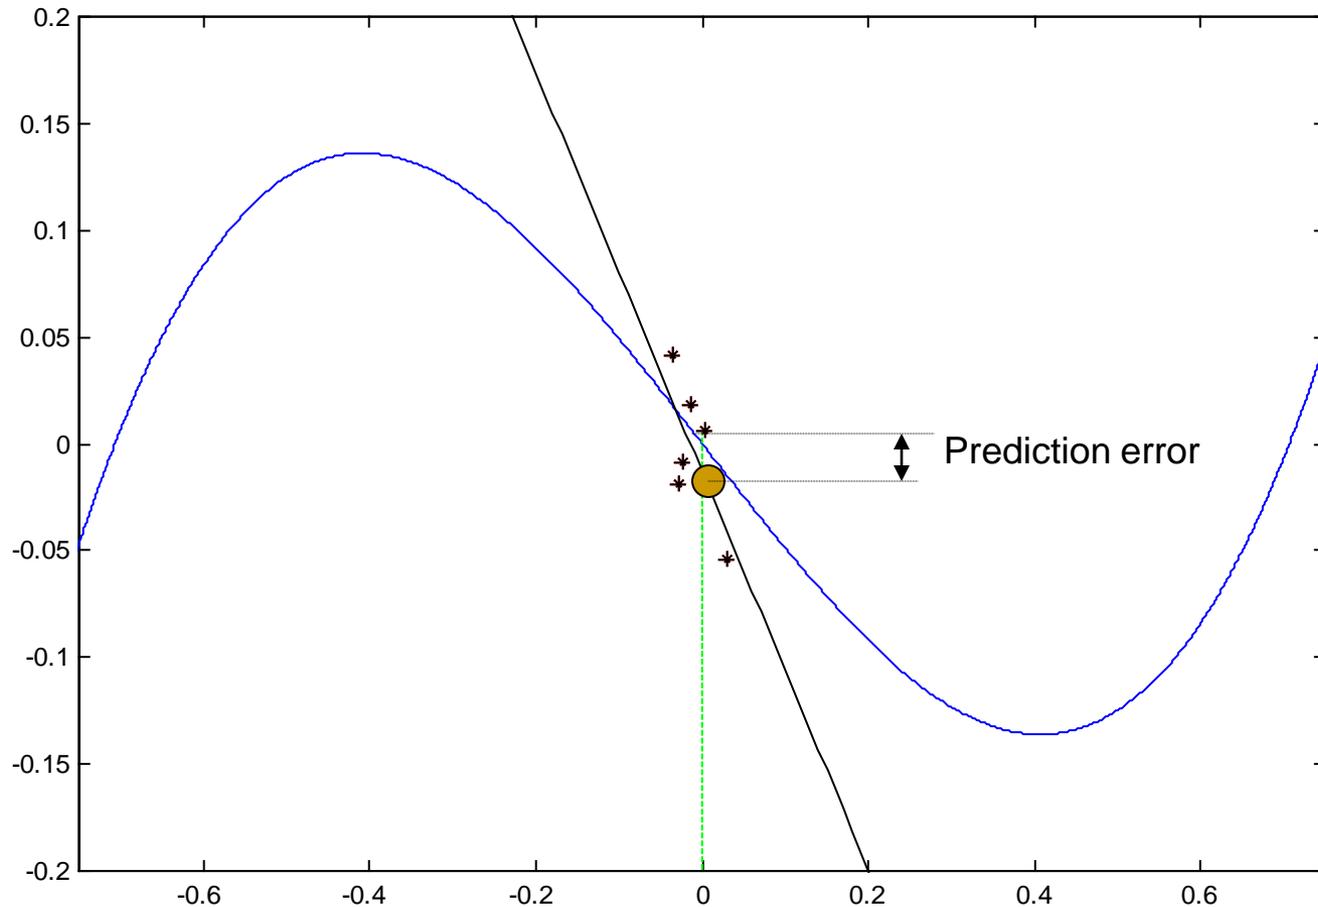

Local modeling procedure

The identification of a local model can be summarized in these steps:

- ◆ **Compute the distance** between the query and the training samples according to a predefined **metric**.
- ◆ **Rank the neighbors** on the basis of their distance to the query.
- ◆ **Select a subset** of the nearest neighbors according to the **bandwidth** which measures the size of the neighborhood.
- ◆ **Fit a local model** (e.g. constant, linear,...).

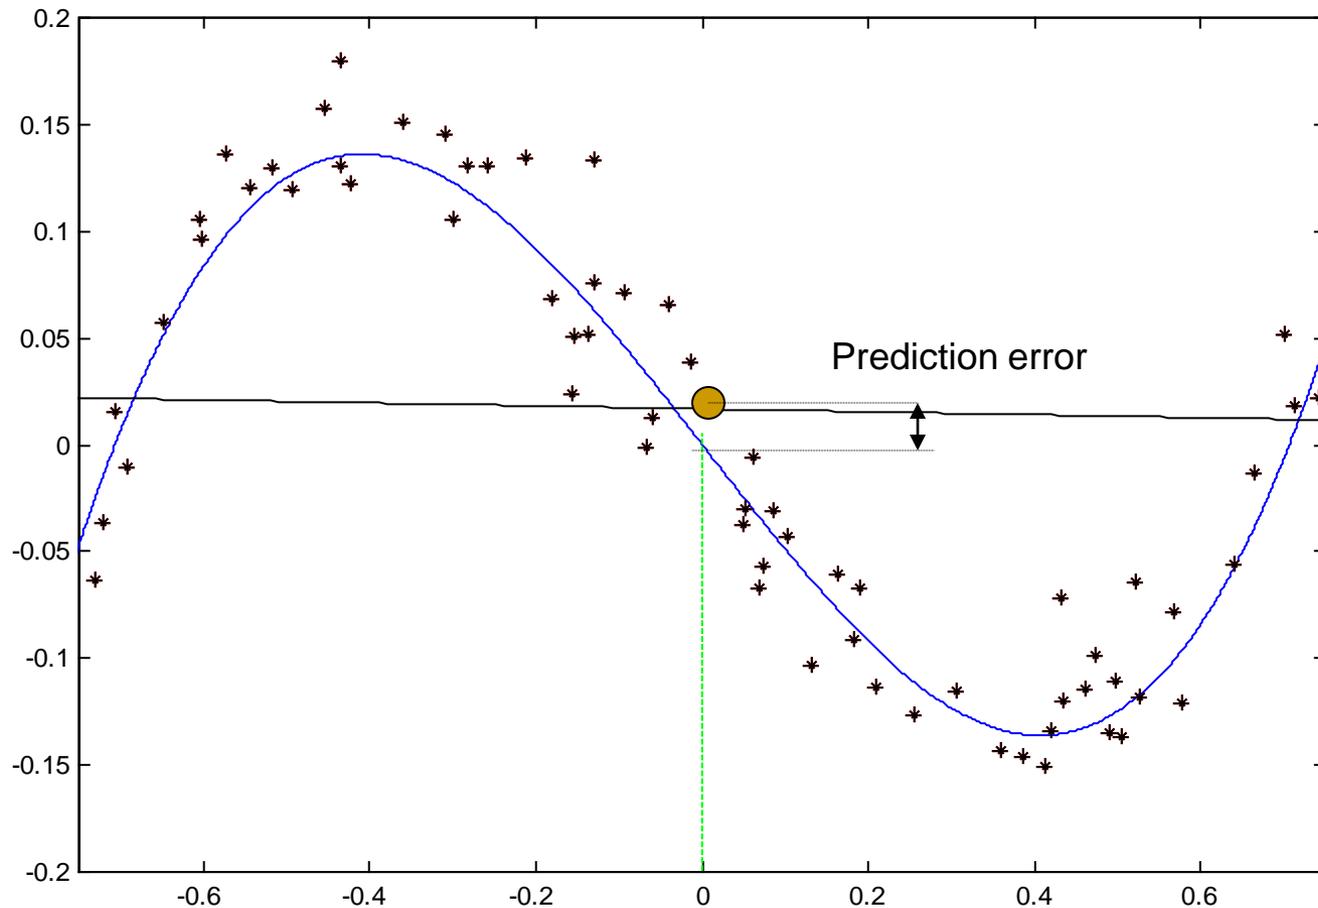

The work focused on the **bandwidth selection problem**.

Bias/variance trade-off: overfitting

too few neighbors \Rightarrow **overfitting** \Rightarrow large prediction error

Bias/variance trade off: underfitting

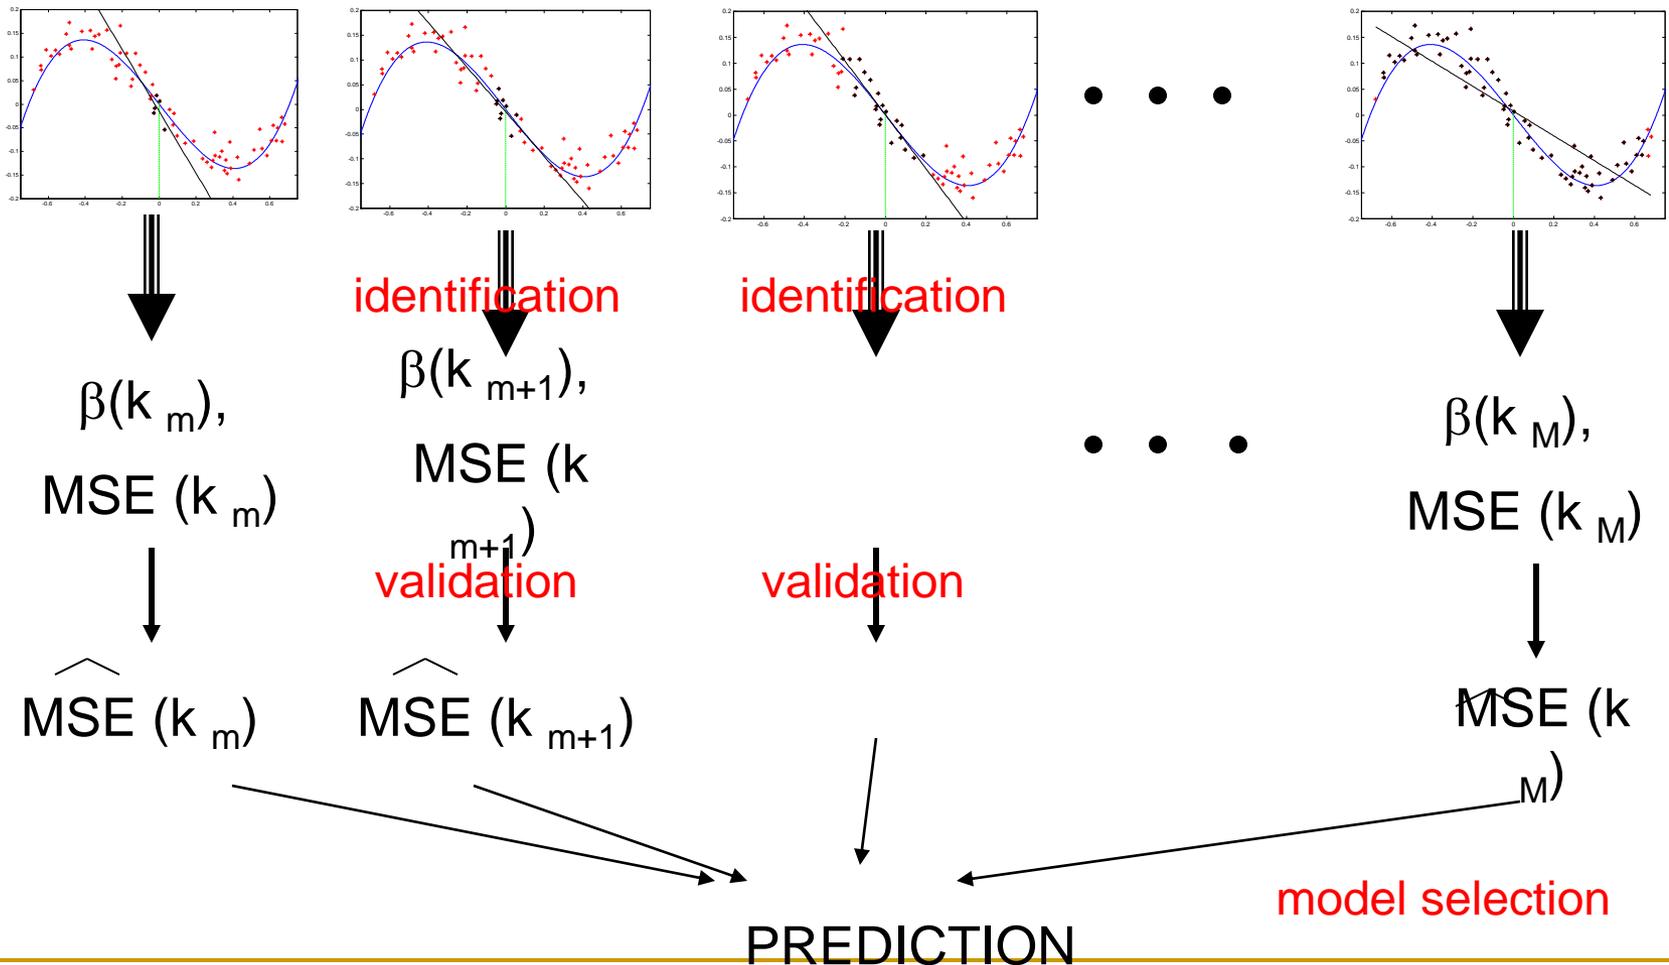

too many neighbors \Rightarrow **underfitting** \Rightarrow large prediction error

Validation croisée: Press

- Fait un leave-one-out sans le faire pour les modèles linéaires
 - Un gain computationnel énorme
 - Rend possible une des validations croisées les plus puissantes à un prix computationnel infime.
-

Data-driven bandwidth selection

Advantages

- No assumption of uniformity
 - Justified in real life
 - Adaptive
 - Simple
-

From local learning to Lazy Learning (LL)

- By speeding up the local learning procedure, we can delay the learning procedure to the moment when a prediction in a query point is required (**query-by-query learning**).
 - This method is called **lazy** since the whole learning procedure is deferred until a prediction is required.
 - Example of non lazy methods (**eager**) are **neural networks** where learning is performed in advance, the fitted model is stored and data are discarded.
-

Static benchmarks

- **Datasets:** 15 **real** and 8 **artificial** datasets from the ML repository.
 - ◆ **Methods:** Lazy Learning, Local modeling, Feed Forward Neural Networks, Mixtures of Experts, Neuro Fuzzy, Regression Trees (Cubist).
 - ◆ **Experimental methodology:** 10-fold cross-validation.
 - ◆ **Results:** Mean absolute error, relative error, **paired t-test**.
-

Observed data

| Dataset | No. examples | No. inputs |
|---------|--------------|------------|
| Housing | 330 | 8 |

Artificial data

| Dataset | No. examples | No. inputs |
|----------|--------------|------------|
| Kin_8nh | 8192 | 8 |
| Kin_8fm | 8192 | 8 |
| Kin_8nm | 8192 | 8 |
| Kin_32fh | 8192 | 32 |
| Kin_32nh | 8192 | 32 |
| Kin_32fm | 8192 | 32 |
| Kin_32 | 8192 | 32 |

Experimental results: paired comparison (I)

Each method compared with all the others ($9 \times 23 = 207$ comparisons)

| Method | No. times significantly worse |
|-------------------------------------|-------------------------------|
| LL linear | 74 |
| LL constant | 96 |
| LL combination | 23 |
| Local modeling linear | 58 |
| Local modeling constant | 81 |
| Cubist | 40 |
| Feed Forward NN | 53 |
| Mixtures of experts | 80 |
| Local Model Network (fuzzy) | 132 |
| Local Model Network (k-mean) | 145 |

The lower, the better !!

Experimental results: paired comparison (II)

Each method compared with all the others ($9 \times 23 = 207$ comparisons)

| Method | No. times significantly better |
|-------------------------------------|--------------------------------|
| LL linear | 80 |
| LL constant | 59 |
| LL combination | 129 |
| Local modeling linear | 89 |
| Local modeling constant | 74 |
| Cubist | 110 |
| Feed Forward NN | 116 |
| Mixtures of experts | 72 |
| Local Model Network (fuzzy) | 32 |
| Local Model Network (k-mean) | 21 |

The larger, the better !!

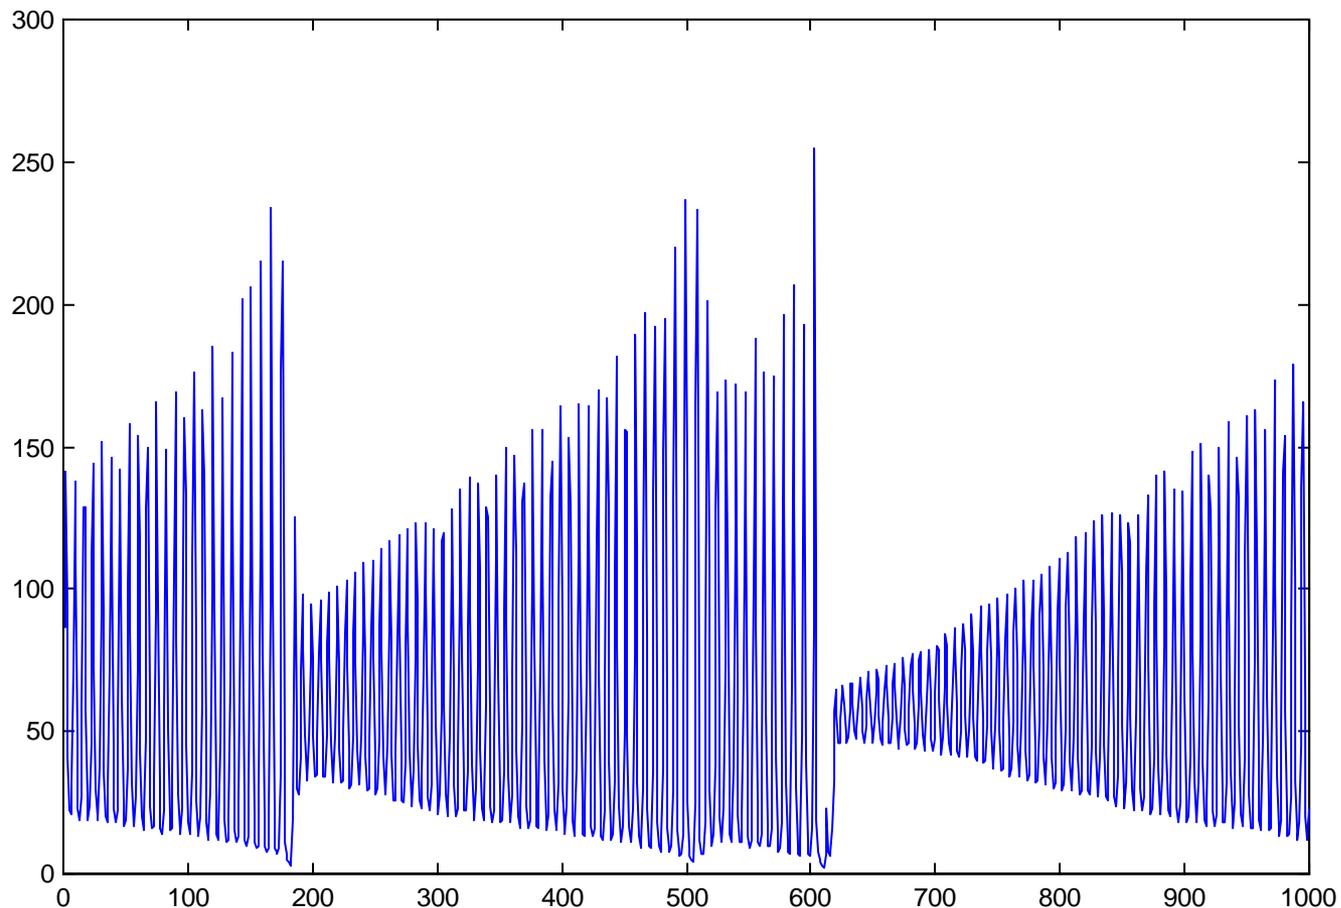

Lazy Learning for dynamic tasks

- long horizon forecasting based on the iteration of a LL one-step-ahead predictor.
 - Nonlinear control
 - Lazy Learning inverse/forward control.
 - Lazy Learning self-tuning control.
 - Lazy Learning optimal control.
-

Dynamic benchmarks

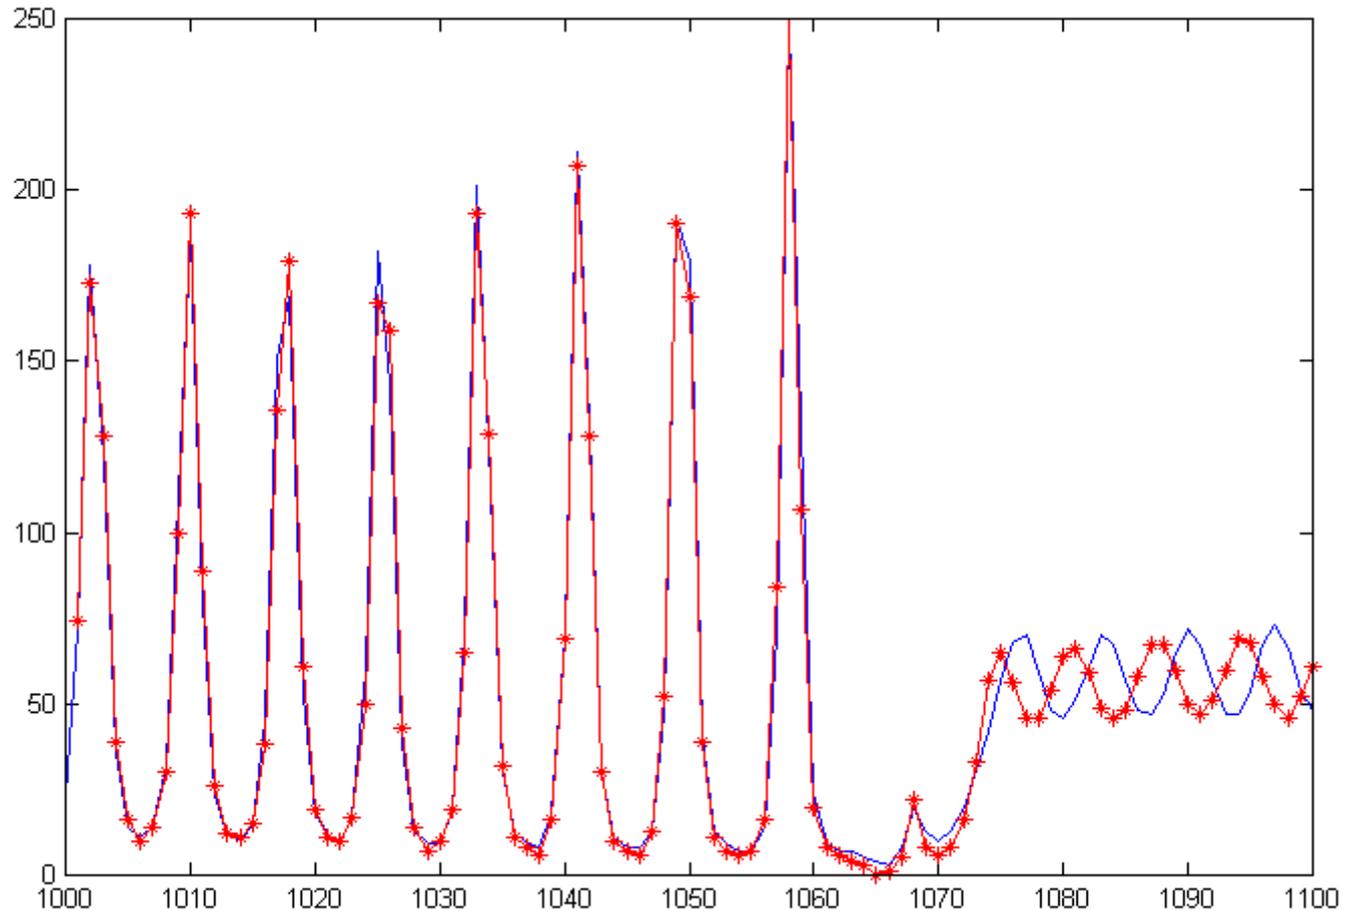

- Multi-step-ahead prediction:
 - Benchmarks: Mackey Glass and 2 Santa Fe time series
 - Referential methods: recurrent neural networks.
 - Nonlinear identification and adaptive control:
 - Benchmarks: Narendra nonlinear plants and bioreactor.
 - Referential methods: neuro-fuzzy controller, neural controller, linear controller.
-

Santa Fe time series

Task: predict the continuation of the series for the next 100 steps.

Lazy Learning prediction

LL is able to predict the abrupt change around $t = 1060$!

Awards in international competitions

- **Data analysis competition:** awarded as a runner-up among 21 participants at the 1999 *CoIL International Competition* on *Protecting rivers and streams by monitoring chemical concentrations and algae communities*.
 - **Time series competition:** ranked second among 17 participants to the *International Competition on Time Series* organized by the *International Workshop on Advanced Black-box techniques for nonlinear modeling* in Leuven, Belgium
-
